671  * unused buffers.  Currently, each freelist holds memory chunks of only a
672  * given size (list->chunklen); other sized chunks are freed and malloced.
673  * This doesn't help much if you're using many different SSL option settings
674  * with a given context.  (The options affecting buffer size are
675  * max_send_fragment, read buffer vs write buffer,
676  * SSL_OP_MICROSOFT_BIG_WRITE_BUFFER, SSL_OP_NO_COMPRESSION, and
677  * SSL_OP_DONT_INSERT_EMPTY_FRAGMENTS.)  Using a separate freelist for every
678  * possible size is not an option, since max_send_fragment can take on many
679  * different values.
680  *
681  * If you are on a platform with a slow malloc(), and you're using SSL
682  * connections with many different settings for these options, and you need to
683  * use the SSL_MOD_RELEASE_BUFFERS feature, you have a few options:
684  *    - Link against a faster malloc implementation.
685  *    - Use a separate SSL_CTX for each option set.
686  *    - Improve this code.

693                  * an SSLv2/v3 compatible client hello). The client_version
694                  * field is the maximum version we permit and it is also
695                  * used in RSA encrypted premaster secrets. Some servers can
696                  * choke if we initially report a higher version then
697                  * renegotiate to a lower one in the premaster secret. This
698                  * didn't happen with TLS 1.0 as most servers supported it
699                  * but it can with TLS 1.1 or later if the server only supports
700                  * 1.0.
701                  *
702                  * Possible scenario with previous logic:
703                  *      1. Client hello indicates TLS 1.2
704                  *      2. Server hello says TLS 1.0
705                  *      3. RSA encrypted premaster secret uses 1.2.
706                  *      4. Handhaked proceeds using TLS 1.0.
707                  *      5. Server sends hello request to renegotiate.
708                  *      6. Client hello indicates TLS v1.0 as we now
709                  *         know that is maximum server supports.
710                  *      7. Server chokes on RSA encrypted premaster secret
711                  *         containing version 1.0.
712                  *
713                  * For interoperability it should be OK to always use the
714                  * maximum version we support in client hello and then rely
715                  * on the checking of version to ensure the servers isn't
716                  * being inconsistent: for example initially negotiating with
717                  * TLS 1.0 and renegotiating with TLS 1.2. We do this by using
718                  * client_version in client hello and not resetting it to
719                  * the negotiated version.

1526 /* SSL_select_next_proto implements the standard protocol selection. It is
1527  * expected that this function is called from the callback set by
1528  * SSL_CTX_set_next_proto_select_cb.
1529  *
1530  * The protocol data is assumed to be a vector of 8-bit, length prefixed byte
1531  * strings. The length byte itself is not included in the length. A byte
1532  * string of length 0 is invalid. No byte string may be truncated.
1533  *
1534  * The current, but experimental algorithm for selecting the protocol is:
1535  *
1536  * 1) If the server doesn't support NPN then this is indicated to the
1537  * callback. In this case, the client application has to abort the connection
1538  * or have a default application level protocol.
1539  *
1540  * 2) If the server supports NPN, but advertises an empty list then the
1541  * client selects the first protcol in its list, but indicates via the
1542  * API that this fallback case was enacted.
1543  *
1544  * 3) Otherwise, the client finds the first protocol in the server's list
1545  * that it supports and selects this protocol. This is because it's
1546  * assumed that the server has better information about which protocol
1547  * a client should use.
1548  *
1549  * 4) If the client doesn't support any of the server's advertised
1550  * protocols, then this is treated the same as case 2.
1551  *
1552  * It returns either
1553  * OPENSSL_NPN_NEGOTIATED if a common protocol was found, or
1554  * OPENSSL_NPN_NO_OVERLAP if the fallback case was reached.

1021 /* The servername extension is treated as follows:

1023    - Only the hostname type is supported with a maximum length of 255.
1024    - The servername is rejected if too long or if it contains zeros,
1025      in which case an fatal alert is generated.
1026    - The servername field is maintained together with the session cache.
1027    - When a session is resumed, the servername call back invoked in order
1028      to allow the application to position itself to the right context.
1029    - The servername is acknowledged if it is new for a session or when
1030      it is identical to a previously used for the same session.
1031      Applications can control the behaviour.  They can at any time
1032      set a 'desirable' servername for a new SSL object. This can be the
1033      case for example with HTTPS when a Host: header field is received and
1034      a renegotiation is requested. In this case, a possible servername
1035      presented in the new client hello is only acknowledged if it matches
1036      the value of the Host: field.
1037    - Applications must  use SSL_OP_NO_SESSION_RESUMPTION_ON_RENEGOTIATION
1038      if they provide for changing an explicit servername context for the session
1039      i.e. when the session has been established with a servername extension.
1040    - On session reconnect, the servername extension may be absent.
