/* This callback type is used inside SSL_CTX, SSL, and in the functions that set
 * them. It is used to override the generation of SSL/TLS session IDs in a
 * server. Return value should be zero on an error, non-zero to proceed. Also,
 * callbacks should themselves check if the id they generate is unique otherwise
 * the SSL handshake will fail with an error - callbacks can do this using the
 * 'ssl' value they're passed by;
 *      SSL_has_matching_session_id(ssl, id, *id_len)
 * The length value passed in is set at the maximum size the session ID can be.
 * In SSLv2 this is 16 bytes, whereas SSLv3/TLSv1 it is 32 bytes. The callback
 * can alter this length to be less if desired, but under SSLv2 session IDs are
 * supposed to be fixed at 16 bytes so the id will be padded after the callback
 * returns in this case. It is also an error for the callback to set the size to
 * zero. */

/* All the following functions return -1 or NULL on error and in some cases
   (UI_process()) -2 if interrupted or in some other way cancelled.
   When everything is fine, they return 0, a positive value or a non-NULL
   pointer, all depending on their purpose. */

/* Creators and destructor.   */
UI *UI_new(void);
UI *UI_new_method(const UI_METHOD *method);
void UI_free(UI *ui);

/* The following functions are used to add strings to be printed and prompt
   strings to prompt for data.  The names are UI_{add,dup}_<function>_string
   and UI_{add,dup}_input_boolean.

   UI_{add,dup}_<function>_string have the following meanings:
        add     add a text or prompt string.  The pointers given to these
                functions are used verbatim, no copying is done.
        dup     make a copy of the text or prompt string, then add the copy
                to the collection of strings in the user interface.
        <function>
                The function is a name for the functionality that the given
                string shall be used for.  It can be one of:
                        input   use the string as data prompt.
                        verify  use the string as verification prompt.  This
                                is used to verify a previous input.
                        info    use the string for informational output.
                        error   use the string for error output.
   Honestly, there's currently no difference between info and error for the
   moment.

   UI_{add,dup}_input_boolean have the same semantics for "add" and "dup",
   and are typically used when one wants to prompt for a yes/no response.

   All of the functions in this group take a UI and a prompt string.
   The string input and verify addition functions also take a flag argument,
   a buffer for the result to end up with, a minimum input size and a maximum
   input size (the result buffer MUST be large enough to be able to contain
   the maximum number of characters).  Additionally, the verify addition
   functions takes another buffer to compare the result against.
   The boolean input functions take an action description string (which should
   be safe to ignore if the expected user action is obvious, for example with
   a dialog box with an OK button and a Cancel button), a string of acceptable
   characters to mean OK and to mean Cancel.  The two last strings are checked
   to make sure they don't have common characters.  Additionally, the same
   flag argument as for the string input is taken, as well as a result buffer.
   The result buffer is required to be at least one byte long.  Depending on
   the answer, the first character from the OK or the Cancel character strings
   will be stored in the first byte of the result buffer.  No NUL will be
   added, so the result is *not* a string.
```

```
   On success, the all return an index of the added information.  That index
   is usefull when retrieving results with UI_get0_result(). */
int UI_add_input_string(UI *ui, const char *prompt, int flags,
        char *result_buf, int minsize, int maxsize);

/* These are the possible flags.  They can be or'ed together. */
/* Use to have echoing of input */
#define UI_INPUT_FLAG_ECHO              0x01
/* Use a default password.  Where that password is found is completely
   up to the application, it might for example be in the user data set
   with UI_add_user_data().  It is not recommended to have more than
   one input in each UI being marked with this flag, or the application
   might get confused. */
#define UI_INPUT_FLAG_DEFAULT_PWD       0x02

/* The user of these routines may want to define flags of their own.  The core
   UI won't look at those, but will pass them on to the method routines.  They
   must use higher bits so they don't get confused with the UI bits above.
   UI_INPUT_FLAG_USER_BASE tells which is the lowest bit to use.  A good
   example of use is this:

        #define MY_UI_FLAG1     (0x01 << UI_INPUT_FLAG_USER_BASE)

*/
#define UI_INPUT_FLAG_USER_BASE 16

/* The following function helps construct a prompt.  object_desc is a
   textual short description of the object, for example "pass phrase",
   and object_name is the name of the object (might be a card name or
   a file name.
   The returned string shall always be allocated on the heap with
   OPENSSL_malloc(), and need to be free'd with OPENSSL_free().

   If the ui_method doesn't contain a pointer to a user-defined prompt
   constructor, a default string is built, looking like this:

        "Enter {object_desc} for {object_name}:"

   So, if object_desc has the value "pass phrase" and object_name has
   the value "foo.key", the resulting string is:

        "Enter pass phrase for foo.key:"
*/
char *UI_construct_prompt(UI *ui_method,
        const char *object_desc, const char *object_name);

/* The following function is used to store a pointer to user-specific data.
   Any previous such pointer will be returned and replaced.
```

```
   For callback purposes, this function makes a lot more sense than using
   ex_data, since the latter requires that different parts of OpenSSL or
   applications share the same ex_data index.

   Note that the UI_OpenSSL() method completely ignores the user data.
   Other methods may not, however.  */

/* ---------- For method writers ---------- */
/* A method contains a number of functions that implement the low level
   of the User Interface.  The functions are:

        an opener       This function starts a session, maybe by opening
                        a channel to a tty, or by opening a window.
        a writer        This function is called to write a given string,
                        maybe to the tty, maybe as a field label in a
                        window.
        a flusher       This function is called to flush everything that
                        has been output so far.  It can be used to actually
                        display a dialog box after it has been built.
        a reader        This function is called to read a given prompt,
                        maybe from the tty, maybe from a field in a
                        window.  Note that it's called wth all string
```

```
                        structures, not only the prompt ones, so it must
                        check such things itself.
        a closer        This function closes the session, maybe by closing
                        the channel to the tty, or closing the window.

   All these functions are expected to return:

        0       on error.
        1       on success.
        -1      on out-of-band events, for example if some prompting has
                been canceled (by pressing Ctrl-C, for example).  This is
                only checked when returned by the flusher or the reader.

   The way this is used, the opener is first called, then the writer for all
   strings, then the flusher, then the reader for all strings and finally the
   closer.  Note that if you want to prompt from a terminal or other command
   line interface, the best is to have the reader also write the prompts
   instead of having the writer do it.  If you want to prompt from a dialog
   box, the writer can be used to build up the contents of the box, and the
   flusher to actually display the box and run the event loop until all data
   has been given, after which the reader only grabs the given data and puts
   them back into the UI strings.

   All method functions take a UI as argument.  Additionally, the writer and
   the reader take a UI_STRING.

SSL     -> X509_STORE_CTX
                ->X509_STORE

The X509_STORE holds the tables etc for verification stuff.
A X509_STORE_CTX is used while validating a single certificate.
The X509_STORE has X509_LOOKUPs for looking up certs.
The X509_STORE then calls a function to actually verify the
certificate chain.

/* Before including this file (pkcs11.h) (or pkcs11t.h by
 * itself), 6 platform-specific macros must be defined.  These
 * macros are described below, and typical definitions for them
 * are also given.  Be advised that these definitions can depend
 * on both the platform and the compiler used (and possibly also
 * on whether a Cryptoki library is linked statically or
 * dynamically).
 *
 * In addition to defining these 6 macros, the packing convention
 * for Cryptoki structures should be set.  The Cryptoki
 * convention on packing is that structures should be 1-byte
 * aligned.
 *
 * If you're using Microsoft Developer Studio 5.0 to produce
 * Win32 stuff, this might be done by using the following
 * preprocessor directive before including pkcs11.h or pkcs11t.h:
 *
 * #pragma pack(push, cryptoki, 1)
 *
 * and using the following preprocessor directive after including
 * pkcs11.h or pkcs11t.h:
 *
 * #pragma pack(pop, cryptoki)
 *
 * If you're using an earlier version of Microsoft Developer
 * Studio to produce Win16 stuff, this might be done by using
 * the following preprocessor directive before including
 * pkcs11.h or pkcs11t.h:
 *
 * #pragma pack(1)
 *
 * In a UNIX environment, you're on your own for this.  You might
 * not need to do (or be able to do!) anything.
 *
 *
 * Now for the macros:
```

```
 *
 *
 * 1. CK_PTR: The indirection string for making a pointer to an
 * object.  It can be used like this:
 *
 * typedef CK_BYTE CK_PTR CK_BYTE_PTR;
 *
 * If you're using Microsoft Developer Studio 5.0 to produce
 * Win32 stuff, it might be defined by:
 *
 * #define CK_PTR *
 *
 * If you're using an earlier version of Microsoft Developer
 * Studio to produce Win16 stuff, it might be defined by:
 *
 * #define CK_PTR far *
 *
 * In a typical UNIX environment, it might be defined by:
 *
 * #define CK_PTR *
 *
 *
 * 2. CK_DEFINE_FUNCTION(returnType, name): A macro which makes
 * an exportable Cryptoki library function definition out of a
 * return type and a function name.  It should be used in the
 * following fashion to define the exposed Cryptoki functions in
 * a Cryptoki library:
 *
 * CK_DEFINE_FUNCTION(CK_RV, C_Initialize)(
 *   CK_VOID_PTR pReserved
 * )
 * {
 *   ...
 * }
 *
 * If you're using Microsoft Developer Studio 5.0 to define a
 * function in a Win32 Cryptoki .dll, it might be defined by:
 *
 * #define CK_DEFINE_FUNCTION(returnType, name) \
 *   returnType __declspec(dllexport) name
 *
 * If you're using an earlier version of Microsoft Developer
 * Studio to define a function in a Win16 Cryptoki .dll, it
 * might be defined by:
 *
 * #define CK_DEFINE_FUNCTION(returnType, name) \
 *   returnType __export _far _pascal name
 *
 * In a UNIX environment, it might be defined by:
 *
 * #define CK_DEFINE_FUNCTION(returnType, name) \
 *   returnType name
 *
 *
 * 3. CK_DECLARE_FUNCTION(returnType, name): A macro which makes
 * an importable Cryptoki library function declaration out of a
 * return type and a function name.  It should be used in the
 * following fashion:
 *
 * extern CK_DECLARE_FUNCTION(CK_RV, C_Initialize)(
 *   CK_VOID_PTR pReserved
 * );
 *
 * If you're using Microsoft Developer Studio 5.0 to declare a
 * function in a Win32 Cryptoki .dll, it might be defined by:
 *
```

```
 * #define CK_DECLARE_FUNCTION(returnType, name) \
 *   returnType __declspec(dllimport) name
 *
 * If you're using an earlier version of Microsoft Developer
 * Studio to declare a function in a Win16 Cryptoki .dll, it
 * might be defined by:
 *
 * #define CK_DECLARE_FUNCTION(returnType, name) \
 *   returnType __export _far _pascal name
 *
 * In a UNIX environment, it might be defined by:
 *
 * #define CK_DECLARE_FUNCTION(returnType, name) \
 *   returnType name
 *
 *
 * 4. CK_DECLARE_FUNCTION_POINTER(returnType, name): A macro
 * which makes a Cryptoki API function pointer declaration or
 * function pointer type declaration out of a return type and a
 * function name.  It should be used in the following fashion:
 *
 * // Define funcPtr to be a pointer to a Cryptoki API function
 * // taking arguments args and returning CK_RV.
 * CK_DECLARE_FUNCTION_POINTER(CK_RV, funcPtr)(args);
 *
 * or
 *
 * // Define funcPtrType to be the type of a pointer to a
 * // Cryptoki API function taking arguments args and returning
 * // CK_RV, and then define funcPtr to be a variable of type
 * // funcPtrType.
 * typedef CK_DECLARE_FUNCTION_POINTER(CK_RV, funcPtrType)(args);
 * funcPtrType funcPtr;
 *
 * If you're using Microsoft Developer Studio 5.0 to access
 * functions in a Win32 Cryptoki .dll, in might be defined by:
 *
 * #define CK_DECLARE_FUNCTION_POINTER(returnType, name) \
 *   returnType __declspec(dllimport) (* name)
 *
 * If you're using an earlier version of Microsoft Developer
 * Studio to access functions in a Win16 Cryptoki .dll, it might
 * be defined by:
 *
 * #define CK_DECLARE_FUNCTION_POINTER(returnType, name) \
 *   returnType __export _far _pascal (* name)
 *
 * In a UNIX environment, it might be defined by:
 *
 * #define CK_DECLARE_FUNCTION_POINTER(returnType, name) \
 *   returnType (* name)
 *
 *
 * 5. CK_CALLBACK_FUNCTION(returnType, name): A macro which makes
 * a function pointer type for an application callback out of
 * a return type for the callback and a name for the callback.
 * It should be used in the following fashion:
 *
 * CK_CALLBACK_FUNCTION(CK_RV, myCallback)(args);
 *
 * to declare a function pointer, myCallback, to a callback
 * which takes arguments args and returns a CK_RV.  It can also
 * be used like this:
 *
 * typedef CK_CALLBACK_FUNCTION(CK_RV, myCallbackType)(args);
 * myCallbackType myCallback;
```

```
 *
 * If you're using Microsoft Developer Studio 5.0 to do Win32
 * Cryptoki development, it might be defined by:
 *
 * #define CK_CALLBACK_FUNCTION(returnType, name) \
 *   returnType (* name)
 *
 * If you're using an earlier version of Microsoft Developer
 * Studio to do Win16 development, it might be defined by:
 *
 * #define CK_CALLBACK_FUNCTION(returnType, name) \
 *   returnType _far _pascal (* name)
 *
 * In a UNIX environment, it might be defined by:
 *
 * #define CK_CALLBACK_FUNCTION(returnType, name) \
 *   returnType (* name)
 *
 *
 * 6. NULL_PTR: This macro is the value of a NULL pointer.
 *
 * In any ANSI/ISO C environment (and in many others as well),
 * this should best be defined by
 *
 * #ifndef NULL_PTR
 * #define NULL_PTR 0
 * #endif

/*
 * This converts an ASN1 INTEGER into its content encoding.
 * The internal representation is an ASN1_STRING whose data is a big endian
 * representation of the value, ignoring the sign. The sign is determined by
 * the type: V_ASN1_INTEGER for positive and V_ASN1_NEG_INTEGER for negative.
 *
 * Positive integers are no problem: they are almost the same as the DER
 * encoding, except if the first byte is >= 0x80 we need to add a zero pad.
 *
 * Negative integers are a bit trickier...
 * The DER representation of negative integers is in 2s complement form.
 * The internal form is converted by complementing each octet and finally
 * adding one to the result. This can be done less messily with a little trick.
 * If the internal form has trailing zeroes then they will become FF by the
 * complement and 0 by the add one (due to carry) so just copy as many trailing
 * zeros to the destination as there are in the source. The carry will add one
 * to the last none zero octet: so complement this octet and add one and finally
 * complement any left over until you get to the start of the string.
 *
 * Padding is a little trickier too. If the first bytes is > 0x80 then we pad
 * with 0xff. However if the first byte is 0x80 and one of the following bytes
 * is non-zero we pad with 0xff. The reason for this distinction is that 0x80
 * followed by optional zeros isn't padded.

/* Experimental NDEF ASN1 BIO support routines */

/* The usage is quite simple, initialize an ASN1 structure,
 * get a BIO from it then any data written through the BIO
 * will end up translated to approptiate format on the fly.
 * The data is streamed out and does *not* need to be
 * all held in memory at once.
 *
 * When the BIO is flushed the output is finalized and any
 * signatures etc written out.
 *
 * The BIO is a 'proper' BIO and can handle non blocking I/O
 * correctly.
 *
 * The usage is simple. The implementation is *not*...

/* X509_REQ_INFO is handled in an unusual way to get round
 * invalid encodings. Some broken certificate requests don't
 * encode the attributes field if it is empty. This is in
 * violation of PKCS#10 but we need to tolerate it. We do
 * this by making the attributes field OPTIONAL then using
 * the callback to initialise it to an empty STACK.
 *
 * This means that the field will be correctly encoded unless
 * we NULL out the field.
 *
 * As a result we no longer need the req_kludge field because
 * the information is now contained in the attributes field:
 * 1. If it is NULL then it's the invalid omission.
 * 2. If it is empty it is the correct encoding.
 * 3. If it is not empty then some attributes are present.
 *
