834         struct {
835         /*
836          * As for following union. Trouble is that there are platforms
837          * that have socklen_t and there are platforms that don't, on
838          * some platforms socklen_t is int and on some size_t. So what
839          * one can do? One can cook #ifdef spaghetti, which is nothing
840          * but masochistic. Or one can do union between int and size_t.
841          * One naturally does it primarily for 64-bit platforms where
842          * sizeof(int) != sizeof(size_t). But would it work? Note that
843          * if size_t member is initialized to 0, then later int member
844          * assignment naturally does the job on little-endian platforms
845          * regardless accept's expectations! What about big-endians?
846          * If accept expects int*, then it works, and if size_t*, then
847          * length value would appear as unreasonably large. But this
848          * won't prevent it from filling in the address structure. The
849          * trouble of course would be if accept returns more data than
850          * actual buffer can accomodate and overwrite stack... That's
851          * where early OPENSSL_assert comes into picture. Besides, the
852          * only 64-bit big-endian platform found so far that expects
853          * size_t* is HP-UX, where stack grows towards higher address.

/*
        Why BIO_s_log?

        BIO_s_log is useful for system daemons (or services under NT).
        It is one-way BIO, it sends all stuff to syslogd (on system that
        commonly use that), or event log (on NT), or OPCOM (on OpenVMS).

/* TODO list
 *
 * 1. Check a bunch of "(words+1)" type hacks in various bignum functions and
 * check they can be safely removed.
 *  - Check +1 and other ugliness in BN_from_montgomery()
 *
 * 2. Consider allowing a BN_new_ex() that, at least, lets you specify an
 * appropriate 'block' size that will be honoured by bn_expand_internal() to
 * prevent piddly little reallocations. OTOH, profiling bignum expansions in
 * BN_CTX doesn't show this to be a big issue.

/*
 * x86_64 BIGNUM accelerator version 0.1, December 2002.
 *
 * Implemented by Andy Polyakov <appro@fy.chalmers.se> for the OpenSSL
 * project.
 *
 * Rights for redistribution and usage in source and binary forms are
 * granted according to the OpenSSL license. Warranty of any kind is
 * disclaimed.
 *
 * Q. Version 0.1? It doesn't sound like Andy, he used to assign real
 *    versions, like 1.0...
 * A. Well, that's because this code is basically a quick-n-dirty
 *    proof-of-concept hack. As you can see it's implemented with
 *    inline assembler, which means that you're bound to GCC and that
 *    there might be enough room for further improvement.
 *
 * Q. Why inline assembler?
 * A. x86_64 features own ABI which I'm not familiar with. This is
 *    why I decided to let the compiler take care of subroutine
 *    prologue/epilogue as well as register allocation. For reference.
 *    Win64 implements different ABI for AMD64, different from Linux.
 *
 * Q. How much faster does it get?
 * A. 'apps/openssl speed rsa dsa' output with no-asm:
 *
 *                      sign    verify    sign/s verify/s
 *      rsa  512 bits   0.0006s   0.0001s   1683.8  18456.2
 *      rsa 1024 bits   0.0028s   0.0002s    356.0   6407.0
 *      rsa 2048 bits   0.0172s   0.0005s     58.0   1957.8
 *      rsa 4096 bits   0.1155s   0.0018s      8.7    555.6
 *                      sign    verify    sign/s verify/s
 *      dsa  512 bits   0.0005s   0.0006s   2100.8   1768.3
 *      dsa 1024 bits   0.0014s   0.0018s    692.3    559.2
 *      dsa 2048 bits   0.0049s   0.0061s    204.7    165.0
 *
 *    'apps/openssl speed rsa dsa' output with this module:
 *
 *                      sign    verify    sign/s verify/s
 *      rsa  512 bits   0.0004s   0.0000s   2767.1  33297.9
 *      rsa 1024 bits   0.0012s   0.0001s    867.4  14674.7
 *      rsa 2048 bits   0.0061s   0.0002s    164.0   5270.0
 *      rsa 4096 bits   0.0384s   0.0006s     26.1   1650.8
 *                      sign    verify    sign/s verify/s
 *      dsa  512 bits   0.0002s   0.0003s   4442.2   3786.3
 *      dsa 1024 bits   0.0005s   0.0007s   1835.1   1497.4
 *      dsa 2048 bits   0.0016s   0.0020s    620.4    504.6
 *
 *    For the reference. IA-32 assembler implementation performs
 *    very much like 64-bit code compiled with no-asm on the same
 *    machine.

/* We generate DH parameters as follows
 * find a prime q which is prime_len/2 bits long.
 * p=(2*q)+1 or (p-1)/2 = q
 * For this case, g is a generator if
 * g^((p-1)/q) mod p != 1 for values of q which are the factors of p-1.
 * Since the factors of p-1 are q and 2, we just need to check
 * g^2 mod p != 1 and g^q mod p != 1.
 *
 * Having said all that,
 * there is another special case method for the generators 2, 3 and 5.
 * for 2, p mod 24 == 11
 * for 3, p mod 12 == 5  <<<<< does not work for safe primes.
 * for 5, p mod 10 == 3 or 7
 *
 * Thanks to Phil Karn <karn@qualcomm.com> for the pointers about the
 * special generators and for answering some of my questions.
 *
 * I've implemented the second simple method :-).
 * Since DH should be using a safe prime (both p and q are prime),
 * this generator function can take a very very long time to run.
