/*
 * IMPLEMENTATION NOTES.
 *
 * As you might have noticed 32-bit hash algorithms:
 *
 * - permit SHA_LONG to be wider than 32-bit (case on CRAY);
 * - optimized versions implement two transform functions: one operating
 *   on [aligned] data in host byte order and one - on data in input
 *   stream byte order;
 * - share common byte-order neutral collector and padding function
 *   implementations, ../md32_common.h;
 *
 * Neither of the above applies to this SHA-512 implementations. Reasons
 * [in reverse order] are:
 *
 * - it's the only 64-bit hash algorithm for the moment of this writing,
 *   there is no need for common collector/padding implementation [yet];
 * - by supporting only one transform function [which operates on
 *   *aligned* data in input stream byte order, big-endian in this case]
 *   we minimize burden of maintenance in two ways: a) collector/padding
 *   function is simpler; b) only one transform function to stare at;
 * - SHA_LONG64 is required to be exactly 64-bit in order to be able to
 *   apply a number of optimizations to mitigate potential performance
 *   penalties caused by previous design decision;
 *
 * Caveat lector.
 *
 * Implementation relies on the fact that "long long" is 64-bit on
 * both 32- and 64-bit platforms. If some compiler vendor comes up
 * with 128-bit long long, adjustment to sha.h would be required.
 * As this implementation relies on 64-bit integer type, it's totally
 * inappropriate for platforms which don't support it, most notably
 * 16-bit platforms.
 *                                      <appro@fy.chalmers.se>

/* This function determines how parameters are "inherited" from one structure
 * to another. There are several different ways this can happen.
 *
 * 1. If a child structure needs to have its values initialized from a parent
 *    they are simply copied across. For example SSL_CTX copied to SSL.
 * 2. If the structure should take on values only if they are currently unset.
 *    For example the values in an SSL structure will take appropriate value
 *    for SSL servers or clients but only if the application has not set new
 *    ones.
 *
 * The "inh_flags" field determines how this function behaves.
 *
 * Normally any values which are set in the default are not copied from the
 * destination and verify flags are ORed together.
 *
 * If X509_VP_FLAG_DEFAULT is set then anything set in the source is copied
 * to the destination. Effectively the values in "to" become default values
 * which will be used only if nothing new is set in "from".
 *
 * If X509_VP_FLAG_OVERWRITE is set then all value are copied across whether
 * they are set or not. Flags is still Ored though.
 *
 * If X509_VP_FLAG_RESET_FLAGS is set then the flags value is copied instead
 * of ORed.
 *
```

```
 * If X509_VP_FLAG_LOCKED is set then no values are copied.
 *
 * If X509_VP_FLAG_ONCE is set then the current inh_flags setting is zeroed
 * after the next call.
