/*
 * As stated in v2.20, 11.7 Object Management Function, in section for
 * C_FindObjectsInit(), at most one search operation may be active at a given
 * time in a given session. Therefore, C_Find{,Init,Final}Objects() should be
 * grouped together to form one atomic search operation. This is already
 * ensured by the property of unique PKCS#11 session handle used for each
 * PK11_SESSION object.
 *
 * This is however not the biggest concern - maintaining consistency of the
 * underlying object store is more important. The same section of the spec also
 * says that one thread can be in the middle of a search operation while another
 * thread destroys the object matching the search template which would result in
 * invalid handle returned from the search operation.
 *
 * Hence, the following locks are used for both protection of the object stores.
 * They are also used for active list protection.

3403 #ifdef  SOLARIS_HW_SLOT_SELECTION
3404 /*
3405  * It would be great if we could use pkcs11_kernel directly since this library
3406  * offers hardware slots only. That's the easiest way to achieve the situation
3407  * where we use the hardware accelerators when present and OpenSSL native code
3408  * otherwise. That presumes the fact that OpenSSL native code is faster than the
3409  * code in the soft token. It's a logical assumption - Crypto Framework has some
3410  * inherent overhead so going there for the software implementation of a
3411  * mechanism should be logically slower in contrast to the OpenSSL native code,
3412  * presuming that both implementations are of similar speed. For example, the
3413  * soft token for AES is roughly three times slower than OpenSSL for 64 byte
3414  * blocks and still 20% slower for 8KB blocks. So, if we want to ship products
3415  * that use the PKCS#11 engine by default, we must somehow avoid that regression
3416  * on machines without hardware acceleration. That's why switching to the
3417  * pkcs11_kernel library seems like a very good idea.
3418  *
3419  * The problem is that OpenSSL built with SunStudio is roughly 2x slower for
3420  * asymmetric operations (RSA/DSA/DH) than the soft token built with the same
3421  * compiler. That means that if we switched to pkcs11_kernel from the libpkcs11
3422  * library, we would have had a performance regression on machines without
3423  * hardware acceleration for asymmetric operations for all applications that use
3424  * the PKCS#11 engine. There is one such application - Apache web server since
3425  * it's shipped configured to use the PKCS#11 engine by default. Having said
3426  * that, we can't switch to the pkcs11_kernel library now and have to come with
3427  * a solution that, on non-accelerated machines, uses the OpenSSL native code
```

```
3428  * for all symmetric ciphers and digests while it uses the soft token for
3429  * asymmetric operations.
3430  *
3431  * This is the idea: dlopen() pkcs11_kernel directly and find out what
3432  * mechanisms are there. We don't care about duplications (more slots can
3433  * support the same mechanism), we just want to know what mechanisms can be
3434  * possibly supported in hardware on that particular machine. As said before,
3435  * pkcs11_kernel will show you hardware providers only.
3436  *
3437  * Then, we rely on the fact that since we use libpkcs11 library we will find
3438  * the metaslot. When we go through the metaslot's mechanisms for symmetric
3439  * ciphers and digests, we check that any found mechanism is in the table
3440  * created using the pkcs11_kernel library. So, as a result we have two arrays
3441  * of mechanisms that were advertised as supported in hardware which was the
3442  * goal of that whole excercise. Thus, we can use libpkcs11 but avoid soft token
3443  * code for symmetric ciphers and digests. See pk11_choose_slots() for more
3444  * information.
3445  *
3446  * This is Solaris specific code, if SOLARIS_HW_SLOT_SELECTION is not defined
3447  * the code won't be used.
3448  */

/*
        From: Arne Ansper <arne@cyber.ee>
```

```
        Why BIO_f_reliable?

        I wrote function which took BIO* as argument, read data from it
        and processed it. Then I wanted to store the input file in
        encrypted form. OK I pushed BIO_f_cipher to the BIO stack
        and everything was OK. BUT if user types wrong password
        BIO_f_cipher outputs only garbage and my function crashes. Yes
        I can and I should fix my function, but BIO_f_cipher is
        easy way to add encryption support to many existing applications
        and it's hard to debug and fix them all.

        So I wanted another BIO which would catch the incorrect passwords and
        file damages which cause garbage on BIO_f_cipher's output.

        The easy way is to push the BIO_f_md and save the checksum at
        the end of the file. However there are several problems with this
        approach:

        1) you must somehow separate checksum from actual data.
        2) you need lot's of memory when reading the file, because you
        must read to the end of the file and verify the checksum before
        letting the application to read the data.

        BIO_f_reliable tries to solve both problems, so that you can
        read and write arbitrary long streams using only fixed amount
        of memory.

        BIO_f_reliable splits data stream into blocks. Each block is prefixed
        with it's length and suffixed with it's digest. So you need only
        several Kbytes of memory to buffer single block before verifying
        it's digest.

        BIO_f_reliable goes further and adds several important capabilities:

        1) the digest of the block is computed over the whole stream
        -- so nobody can rearrange the blocks or remove or replace them.

        2) to detect invalid passwords right at the start BIO_f_reliable
        adds special prefix to the stream. In order to avoid known plain-text
        attacks this prefix is generated as follows:

                *) digest is initialized with random seed instead of
                standardized one.
                *) same seed is written to output
                *) well-known text is then hashed and the output
                of the digest is also written to output.

        reader can now read the seed from stream, hash the same string
        and then compare the digest output.

        Bad things: BIO_f_reliable knows what's going on in EVP_Digest. I
        initially wrote and tested this code on x86 machine and wrote the
        digests out in machine-dependent order :( There are people using
        this code and I cannot change this easily without making existing
        data files unreadable.

/*
 * Overhaul notes;
 *
 * This code is now *mostly* thread-safe. It is now easier to understand in what
 * ways it is safe and in what ways it is not, which is an improvement. Firstly,
 * all per-class stacks and index-counters for ex_data are stored in the same
 * global LHASH table (keyed by class). This hash table uses locking for all
 * access with the exception of CRYPTO_cleanup_all_ex_data(), which must only be
 * called when no other threads can possibly race against it (even if it was
 * locked, the race would mean it's possible the hash table might have been
 * recreated after the cleanup). As classes can only be added to the hash table,
 * and within each class, the stack of methods can only be incremented, the
 * locking mechanics are simpler than they would otherwise be. For example, the
 * new/dup/free ex_data functions will lock the hash table, copy the method
 * pointers it needs from the relevant class, then unlock the hash table before
 * actually applying those method pointers to the task of the new/dup/free
 * operations. As they can't be removed from the method-stack, only
 * supplemented, there's no race conditions associated with using them outside
 * the lock. The get/set_ex_data functions are not locked because they do not
 * involve this global state at all - they operate directly with a previously
 * obtained per-class method index and a particular "ex_data" variable. These
 * variables are usually instantiated per-context (eg. each RSA structure has
 * one) so locking on read/write access to that variable can be locked locally
 * if required (eg. using the "RSA" lock to synchronise access to a
 * per-RSA-structure ex_data variable if required).
 * [Geoff]

/* Code for dynamic hash table routines
 * Author - Eric Young v 2.0
 *
```

```
 * 2.2 eay - added #include "crypto.h" so the memory leak checking code is
 *           present. eay 18-Jun-98
 *
 * 2.1 eay - Added an 'error in last operation' flag. eay 6-May-98
 *
 * 2.0 eay - Fixed a bug that occurred when using lh_delete
 *           from inside lh_doall().  As entries were deleted,
 *           the 'table' was 'contract()ed', making some entries
 *           jump from the end of the table to the start, there by
 *           skipping the lh_doall() processing. eay - 4/12/95
 *
 * 1.9 eay - Fixed a memory leak in lh_free, the LHASH_NODEs
 *           were not being free()ed. 21/11/95
 *
 * 1.8 eay - Put the stats routines into a separate file, lh_stats.c
 *           19/09/95
 *
 * 1.7 eay - Removed the fputs() for realloc failures - the code
 *           should silently tolerate them.  I have also fixed things
 *           lint complained about 04/05/95
 *
 * 1.6 eay - Fixed an invalid pointers in contract/expand 27/07/92
 *
 * 1.5 eay - Fixed a misuse of realloc in expand 02/03/1992
 *
 * 1.4 eay - Fixed lh_doall so the function can call lh_delete 28/05/91
 *
 * 1.3 eay - Fixed a few lint problems 19/3/1991
 *
 * 1.2 eay - Fixed lh_doall problem 13/3/1991
 *
 * 1.1 eay - Added lh_doall
 *
 * 1.0 eay - First version

/*
 * Trouble with Ciphertext Stealing, CTS, mode is that there is no
 * common official specification, but couple of cipher/application
 * specific ones: RFC2040 and RFC3962. Then there is 'Proposal to
 * Extend CBC Mode By "Ciphertext Stealing"' at NIST site, which
 * deviates from mentioned RFCs. Most notably it allows input to be
 * of block length and it doesn't flip the order of the last two
 * blocks. CTS is being discussed even in ECB context, but it's not
 * adopted for any known application. This implementation provides
 * two interfaces: one compliant with above mentioned RFCs and one
 * compliant with the NIST proposal, both extending CBC mode.

/*
 * Even though permitted values for TABLE_BITS are 8, 4 and 1, it should
 * never be set to 8. 8 is effectively reserved for testing purposes.
 * TABLE_BITS>1 are lookup-table-driven implementations referred to as
 * "Shoup's" in GCM specification. In other words OpenSSL does not cover
 * whole spectrum of possible table driven implementations. Why? In
 * non-"Shoup's" case memory access pattern is segmented in such manner,
 * that it's trivial to see that cache timing information can reveal
 * fair portion of intermediate hash value. Given that ciphertext is
 * always available to attacker, it's possible for him to attempt to
 * deduce secret parameter H and if successful, tamper with messages
 * [which is nothing but trivial in CTR mode]. In "Shoup's" case it's
 * not as trivial, but there is no reason to believe that it's resistant
 * to cache-timing attack. And the thing about "8-bit" implementation is
 * that it consumes 16 (sixteen) times more memory, 4KB per individual
 * key + 1KB shared. Well, on pros side it should be twice as fast as
 * "4-bit" version. And for gcc-generated x86[_64] code, "8-bit" version
 * was observed to run ~75% faster, closer to 100% for commercial
 * compilers... Yet "4-bit" procedure is preferred, because it's
 * believed to provide better security-performance balance and adequate
 * all-round performance. "All-round" refers to things like:
 *
 * - shorter setup time effectively improves overall timing for
 *   handling short messages;
 * - larger table allocation can become unbearable because of VM
 *   subsystem penalties (for example on Windows large enough free
 *   results in VM working set trimming, meaning that consequent
 *   malloc would immediately incur working set expansion);
 * - larger table has larger cache footprint, which can affect
 *   performance of other code paths (not necessarily even from same
 *   thread in Hyper-Threading world);
 *
 * Value of 1 is not appropriate for performance reasons.
