  30 #       Note that libcurses installs commands along with its library.
  31 #       This is a minor bug which probably should be fixed.
  32 #       Note also that a few extra libraries are kept in cmd source.
  33 #
  34 # Certain libraries are linked with, hence depend on, other libraries.
  35 #
  36 # Although we have historically used .WAIT to express dependencies, it
  37 # reduces the amount of parallelism and thus lengthens the time it
  38 # takes to build the libraries.  Thus, we now require that any new
  39 # libraries explicitly call out their dependencies.  Eventually, all
  40 # the library dependencies will be called out explicitly.  See
  41 # "Library interdependencies" near the end of this file.
  42 #
  43 # Aside from explicit dependencies (and legacy .WAITs), all libraries
  44 # are built in parallel.
  45 #
  46 .PARALLEL:

531 .KEEP_STATE:

533 #
534 # For the all and install targets, we clearly must respect library
535 # dependencies so that the libraries link correctly.  However, for
536 # the remaining targets (check, clean, clobber, install_h, lint, _dc
537 # and _msg), libraries do not have any dependencies on one another
538 # and thus respecting dependencies just slows down the build.
539 # As such, for these rules, we use pattern replacement to explicitly
540 # avoid triggering the dependency information.  Note that for clean,
541 # clobber and lint, we must use $(NOWAIT_SUBDIRS) rather than
542 # $(SUBDIRS), to prevent '.WAIT' from expanding to '.WAIT-nodepend'.

 79 /*
 80  * get_cert_chain - Builds a chain of certificates, from a given
 81  * user certificate to a trusted certificate.
 82  *
 83  * Arguments:
 84  * err - Error object to add errors to
 85  * cert - User cert to start with
 86  * cas - Trusted certs to use as trust anchors
 87  * chain - The resulting chain of certs (in the form of an
 88  * ordered set) is placed here.
 89  *
 90  * Returns:
 91  *   0 - Success - chain is stored in 'chain'.

**********************************************************
    1967 Wed Aug 13 19:51:33 2014
new/usr/src/lib/openssl/README
4853 illumos-gate is not lint-clean when built with openssl 1.0
**********************************************************
```

```
  1 This is a private copy of OpenSSL library, used by illumos.
  2 Libraries are renamed to libsunw_crypto.so.1 and libsunw_ssl.so.1.
  3 All global symbols are prefixed by "sunw_" to avoid conflicts
  4 with OpenSSL library provided by distributions.
  5 To use this library with your code you should ensure that it
  6 includes opensslconf.h so that global symbols are transparently
  7 renamed.

  9 Compared to the original OpenSSL version the code is
 10 organized in the following way.
 11 Only files which are used in illumos i386/amd64 build are present.
 12 All private include files are moved to usr/src/lib/openssl/include.
 13 All public include files are moved to usr/src/lib/openssl/include/openssl.
 14 C files from ssl/ are moved to usr/src/lib/openssl/libsunw_ssl,
 15 C files from crypto/ are moved to usr/src/lib/openssl/sunw_crypto,
 16 subdirectory structure  is preserved.
 17 All Perl files used to generate assembler are moved from crypto/perlasm
 18 and crypto/*/asm to usr/src/lib/openssl/libsunw_crypto/pl/.
 19 No plain asm files are used.
 20 Scripts form https://github.com/joyent/illumos-extra/tree/master/openssl1x/tools
 21 were used to generate initial sunw_prefix.h and mapfiles.

 23 The easiest way to update OpenSSL to the next minor version (i.e. form 1.0.1X to
 24 1.0.1X+1) would be just make diff between 1.0.1X and 1.0.1X+1 and manually apply
 25 it to usr/src/lib/openssl.
 26 While doing this, take into consideration the following:
 27 - only diff for files in ssl,crypto and include subdirectories is necessary;
 28 - some files are not present in this copy of OpenSSL, so remove from diff change
 29 to the files which are not present in usr/src/lib/openssl;
 30 - some header files in original OpenSSL version are present in both include
 31 directory and ssl or crypto directories, for such files only diff for files in
 32 include directory is necessary.

 34 You can use check_symbols target to list new unprefixed function symbols which
 35 could be introduced by update. You likely want to add them to mapfile-vers and
 36 sunw_prefix.h files
 37 #endif /* ! codereview */
```

/*
 * BN_window_bits_for_exponent_size -- macro for sliding window mod_exp function
 *
 *
 * For window size 'w' (w >= 2) and a random 'b' bits exponent,
 * the number of multiplications is a constant plus on average
```

```
 *
 *    2^(w-1) + (b-w)/(w+1);
 *
 * here  2^(w-1)  is for precomputing the table (we actually need
 * entries only for windows that have the lowest bit set), and
 * (b-w)/(w+1)  is an approximation for the expected number of
 * w-bit windows, not counting the first one.
 *
 * Thus we should use
 *
 *    w >= 6  if        b > 671
 *     w = 5  if  671 > b > 239
 *     w = 4  if  239 > b >  79
 *     w = 3  if   79 > b >  23
 *    w <= 2  if   23 > b
 *
 * (with draws in between).  Very small exponents are often selected
 * with low Hamming weight, so we use  w = 1  for b <= 23.

 * BN_UMULT_HIGH section.
 *
 * No, I'm not trying to overwhelm you when stating that the
 * product of N-bit numbers is 2*N bits wide:-) No, I don't expect
 * you to be impressed when I say that if the compiler doesn't
 * support 2*N integer type, then you have to replace every N*N
 * multiplication with 4 (N/2)*(N/2) accompanied by some shifts
 * and additions which unavoidably results in severe performance
 * penalties. Of course provided that the hardware is capable of
 * producing 2*N result... That's when you normally start
 * considering assembler implementation. However! It should be
 * pointed out that some CPUs (most notably Alpha, PowerPC and
 * upcoming IA-64 family:-) provide *separate* instruction
 * calculating the upper half of the product placing the result
 * into a general purpose register. Now *if* the compiler supports
 * inline assembler, then it's not impossible to implement the
 * "bignum" routines (and have the compiler optimize 'em)
 * exhibiting "native" performance in C. That's what BN_UMULT_HIGH
 * macro is about:-)
 *

361 #endif

363         /* IP and FP
364          * The problem is more of a geometric problem that random bit fiddling.
365          0  1  2  3  4  5  6  7      62 54 46 38 30 22 14  6
366          8  9 10 11 12 13 14 15      60 52 44 36 28 20 12  4
367         16 17 18 19 20 21 22 23      58 50 42 34 26 18 10  2
368         24 25 26 27 28 29 30 31  to  56 48 40 32 24 16  8  0

370         32 33 34 35 36 37 38 39      63 55 47 39 31 23 15  7
371         40 41 42 43 44 45 46 47      61 53 45 37 29 21 13  5
372         48 49 50 51 52 53 54 55      59 51 43 35 27 19 11  3
373         56 57 58 59 60 61 62 63      57 49 41 33 25 17  9  1

375         The output has been subject to swaps of the form
376         0 1 -> 3 1 but the odd and even bits have been put into
377         2 3    2 0
378         different words.  The main trick is to remember that
379         t=((l>>size)^r)&(mask);
380         r^=t;
381         l^=(t<<size);
382         can be used to swap and move bits between words.

384         So l =  0  1  2  3  r = 16 17 18 19
385                 4  5  6  7      20 21 22 23
386                 8  9 10 11      24 25 26 27
387                12 13 14 15      28 29 30 31
388         becomes (for size == 2 and mask == 0x3333)
389            t =   2^16  3^17 -- --   l =  0  1 16 17  r =  2  3 18 19
390                  6^20  7^21 -- --        4  5 20 21       6  7 22 23
391                 10^24 11^25 -- --        8  9 24 25      10 11 24 25
```

```
392                 14^28 15^29 -- --       12 13 28 29      14 15 28 29

394         Thanks for hints from Richard Outerbridge - he told me IP&FP
395         could be done in 15 xor, 10 shifts and 5 ands.
396         When I finally started to think of the problem in 2D
397         I first got ~42 operations without xors.  When I remembered
398         how to use xors :-) I got it to its final state.
399         */

  /* We don't have any well-defined random devices on VMS, yet... */
#    undef DEVRANDOM
  /* We need to do this since VMS has the following coding on status codes:

     Bits 0-2: status type: 0 = warning, 1 = success, 2 = error, 3 = info ...
               The important thing to know is that odd numbers are considered
               good, while even ones are considered errors.
     Bits 3-15: actual status number
     Bits 16-27: facility number.  0 is considered "unknown"
     Bits 28-31: control bits.  If bit 28 is set, the shell won't try to
                 output the message (which, for random codes, just looks ugly)

     So, what we do here is to change 0 to 1 to get the default success status,
     and everything else is shifted up to fit into the status number field, and
     the status is tagged as an error, which I believe is what is wanted here.

/*
 * This structure encapsulates all reusable information for a PKCS#11
 * session. A list of these objects is created on behalf of the
 * calling application using an on-demand method. Each operation
 * type (see PK11_OPTYPE below) has its own per-process list.
 * Each of the lists is basically a cache for faster PKCS#11 object
 * access to avoid expensive C_Find{,Init,Final}Object() calls.
 *
 * When a new request comes in, an object will be taken from the list
 * (if there is one) or a new one is created to handle the request
 * (if the list is empty). See pk11_get_session() on how it is done.

/*
 * We have 3 different groups of operation types:
 *   1) asymmetric operations
 *   2) random operations
 *   3) symmetric and digest operations
 *
 * This division into groups stems from the fact that it's common that hardware
 * providers may support operations from one group only. For example, hardware
 * providers on UltraSPARC T2, n2rng(7d), ncp(7d), and n2cp(7d), each support
 * only a single group of operations.
 *
 * For every group a different slot can be chosen. That means that we must have
 * at least 3 different lists of cached PKCS#11 sessions since sessions from
 * different groups may be initialized in different slots.
 *
 * To provide locking granularity in multithreaded environment, the groups are
 * further splitted into types with each type having a separate session cache.

/*
 * This is a generic 32 bit "collector" for message digest algorithms.
 * Whenever needed it collects input character stream into chunks of
 * 32 bit values and invokes a block function that performs actual hash
 * calculations.
 *
 * Porting guide.
 *
 * Obligatory macros:
 *
```

```
 * DATA_ORDER_IS_BIG_ENDIAN or DATA_ORDER_IS_LITTLE_ENDIAN
 *      this macro defines byte order of input stream.
 * HASH_CBLOCK
 *      size of a unit chunk HASH_BLOCK operates on.
 * HASH_LONG
 *      has to be at lest 32 bit wide, if it's wider, then
 *      HASH_LONG_LOG2 *has to* be defined along
 * HASH_CTX
 *      context structure that at least contains following
 *      members:
 *              typedef struct {
 *                      ...
 *                      HASH_LONG       Nl,Nh;
 *                      either {
 *                      HASH_LONG       data[HASH_LBLOCK];
 *                      unsigned char   data[HASH_CBLOCK];
 *                      };
 *                      unsigned int    num;
 *                      ...
 *                      } HASH_CTX;
 *      data[] vector is expected to be zeroed upon first call to
 *      HASH_UPDATE.
 * HASH_UPDATE
 *      name of "Update" function, implemented here.
 * HASH_TRANSFORM
 *      name of "Transform" function, implemented here.
 * HASH_FINAL
 *      name of "Final" function, implemented here.
 * HASH_BLOCK_DATA_ORDER
 *      name of "block" function capable of treating *unaligned* input
 *      message in original (data) byte order, implemented externally.
 * HASH_MAKE_STRING
 *      macro convering context variables to an ASCII hash string.
 *
 * MD5 example:
 *
 *      #define DATA_ORDER_IS_LITTLE_ENDIAN
 *
 *      #define HASH_LONG               MD5_LONG
 *      #define HASH_LONG_LOG2          MD5_LONG_LOG2

 * This comment was originaly written for MD5, which is why it
 * discusses A-D. But it basically applies to all 32-bit digests,
 * which is why it was moved to common header file.
```

```
392  *
393  * In case you wonder why A-D are declared as long and not
394  * as MD5_LONG. Doing so results in slight performance
395  * boost on LP64 architectures. The catch is we don't
396  * really care if 32 MSBs of a 64-bit register get polluted
397  * with eventual overflows as we *save* only 32 LSBs in
398  * *either* case. Now declaring 'em long excuses the compiler
399  * from keeping 32 MSBs zeroed resulting in 13% performance
400  * improvement under SPARC Solaris7/64 and 5% under AlphaLinux.
401  * Well, to be honest it should say that this *prevents*
402  * performance degradation.
403  *                              <appro@fy.chalmers.se>
404  */
405 #else
406 /*
407  * Above is not absolute and there are LP64 compilers that
408  * generate better code if MD32_REG_T is defined int. The above

364 /* The following macros and typedefs allow an ASN1_ITEM
365  * to be embedded in a structure and referenced. Since
366  * the ASN1_ITEM pointers need to be globally accessible
367  * (possibly from shared libraries) they may exist in
368  * different forms. On platforms that support it the
369  * ASN1_ITEM structure itself will be globally exported.
370  * Other platforms will export a function that returns
371  * an ASN1_ITEM pointer.
372  *
373  * To handle both cases transparently the macros below
374  * should be used instead of hard coding an ASN1_ITEM
375  * pointer in a structure.
376  *
377  * The structure will look like this:
378  *
379  * typedef struct SOMETHING_st {
380  *      ...
381  *      ASN1_ITEM_EXP *iptr;
382  *      ...
383  * } SOMETHING;
384  *
385  * It would be initialised as e.g.:
386  *
387  * SOMETHING somevar = {...,ASN1_ITEM_ref(X509),...};
388  *
389  * and the actual pointer extracted with:
390  *
391  * const ASN1_ITEM *it = ASN1_ITEM_ptr(somevar.iptr);
```

```
392  *
393  * Finally an ASN1_ITEM pointer can be extracted from an
394  * appropriate reference with: ASN1_ITEM_rptr(X509). This
395  * would be used when a function takes an ASN1_ITEM * argument.
396  *

};

/* These are values for the itype field and
 * determine how the type is interpreted.
 *
 * For PRIMITIVE types the underlying type
 * determines the behaviour if items is NULL.
 *
 * Otherwise templates must contain a single
 * template and the type is treated in the
 * same way as the type specified in the template.
 *
```

```
 * For SEQUENCE types the templates field points
 * to the members, the size field is the
 * structure size.
 *
 * For CHOICE types the templates field points
 * to each possible member (typically a union)
 * and the 'size' field is the offset of the
 * selector.
 *
 * The 'funcs' field is used for application
 * specific functions.
 *
 * For COMPAT types the funcs field gives a
 * set of functions that handle this type, this
 * supports the old d2i, i2d convention.
 *
 * The EXTERN type uses a new style d2i/i2d.
 * The new style should be used where possible
 * because it avoids things like the d2i IMPLICIT
 * hack.
 *
 * MSTRING is a multiple string type, it is used
 * for a CHOICE of character strings where the
 * actual strings all occupy an ASN1_STRING
 * structure. In this case the 'utype' field
 * has a special meaning, it is used as a mask
 * of acceptable types using the B_ASN1 constants.
 *
 * NDEF_SEQUENCE is the same as SEQUENCE except
 * that it will use indefinite length constructed
 * encoding if requested.
 *

707 /* Bignum consistency macros
708  * There is one "API" macro, bn_fix_top(), for stripping leading zeroes from
709  * bignum data after direct manipulations on the data. There is also an
710  * "internal" macro, bn_check_top(), for verifying that there are no leading
711  * zeroes. Unfortunately, some auditing is required due to the fact that
712  * bn_fix_top() has become an overabused duct-tape because bignum data is
713  * occasionally passed around in an inconsistent state. So the following
714  * changes have been made to sort this out;
715  * - bn_fix_top()s implementation has been moved to bn_correct_top()
716  * - if BN_DEBUG isn't defined, bn_fix_top() maps to bn_correct_top(), and
717  *   bn_check_top() is as before.
718  * - if BN_DEBUG *is* defined;
719  *   - bn_check_top() tries to pollute unused words even if the bignum 'top' is
720  *     consistent. (ed: only if BN_DEBUG_RAND is defined)
721  *   - bn_fix_top() maps to bn_check_top() rather than "fixing" anything.
```

```
722  * The idea is to have debug builds flag up inconsistent bignums when they
723  * occur. If that occurs in a bn_fix_top(), we examine the code in question; if
724  * the use of bn_fix_top() was appropriate (ie. it follows directly after code
725  * that manipulates the bignum) it is converted to bn_correct_top(), and if it
726  * was not appropriate, we convert it permanently to bn_check_top() and track
727  * down the cause of the bug. Eventually, no internal code should be using the
728  * bn_fix_top() macro. External applications and libraries should try this with
729  * their own code too, both in terms of building against the openssl headers
730  * with BN_DEBUG defined *and* linking with a version of OpenSSL built with it
731  * defined. This not only improves external code, it provides more test
732  * coverage for openssl's own code.

/* crypto/des/des_old.h -*- mode:C; c-file-style: "eay" -*- */

/* WARNING WARNING WARNING WARNING WARNING WARNING WARNING WARNING
 *
 * The function names in here are deprecated and are only present to
 * provide an interface compatible with openssl 0.9.6 and older as
 * well as libdes.  OpenSSL now provides functions where "des_" has
 * been replaced with "DES_" in the names, to make it possible to
 * make incompatible changes that are needed for C type security and
 * other stuff.
 *
 * This include files has two compatibility modes:
 *
 *   - If OPENSSL_DES_LIBDES_COMPATIBILITY is defined, you get an API
 *     that is compatible with libdes and SSLeay.
 *   - If OPENSSL_DES_LIBDES_COMPATIBILITY isn't defined, you get an
 *     API that is compatible with OpenSSL 0.9.5x to 0.9.6x.
 *
 * Note that these modes break earlier snapshots of OpenSSL, where
 * libdes compatibility was the only available mode or (later on) the
 * prefered compatibility mode.  However, after much consideration
 * (and more or less violent discussions with external parties), it
 * was concluded that OpenSSL should be compatible with earlier versions
 * of itself before anything else.  Also, in all honesty, libdes is
 * an old beast that shouldn't really be used any more.
 *
 * Please consider starting to use the DES_ functions rather than the
 * des_ ones.  The des_ functions will disappear completely before
 * OpenSSL 1.0!

/*
 * Unsolved problem: if a type is actually a pointer type, like
 * nid_triple is, then its impossible to get a const where you need
 * it. Consider:
 *
 * typedef int nid_triple[3];
 * const void *a_;
 * const nid_triple const *a = a_;
 *
 * The assignement discards a const because what you really want is:
 *
 * const int const * const *a = a_;
 *
 * But if you do that, you lose the fact that a is an array of 3 ints,
 * which breaks comparison functions.
 *
 * Thus we end up having to cast, sadly, or unpack the
 * declarations. Or, as I finally did in this case, delcare nid_triple
 * to be a struct, which it should have been in the first place.
 *
 * Ben, August 2008.
```

```
 *
 * Also, strictly speaking not all types need be const, but handling
 * the non-constness means a lot of complication, and in practice
 * comparison routines do always not touch their arguments.

287   /* Note 1:
288      The value for "signature" is specified in the OCSP rfc2560 as follows:
289      "The value for the signature SHALL be computed on the hash of the DER
290      encoding ResponseData."  This means that you must hash the DER-encoded
291      tbsResponseData, and then run it through a crypto-signing function, which
292      will (at least w/RSA) do a hash-'n'-private-encrypt operation.  This seems
293      a bit odd, but that's the spec.  Also note that the data structures do not
294      leave anywhere to independently specify the algorithm used for the initial
295      hash. So, we look at the signature-specification algorithm, and try to do
296      something intelligent.     -- Kathy Weinhold, CertCo */
297   /* Note 2:
298      It seems that the mentioned passage from RFC 2560 (section 4.2.1) is open
299      for interpretation.  I've done tests against another responder, and found
300      that it doesn't do the double hashing that the RFC seems to say one
301      should.  Therefore, all relevant functions take a flag saying which
302      variant should be used.    -- Richard Levitte, OpenSSL team and CeloCom */

/* Numeric release version identifier:
 * MNNFFPPS: major minor fix patch status
 * The status nibble has one of the values 0 for development, 1 to e for betas
 * 1 to 14, and f for release.  The patch level is exactly that.
 * For example:
 * 0.9.3-dev      0x00903000
 * 0.9.3-beta1    0x00903001
 * 0.9.3-beta2-dev 0x00903002
 * 0.9.3-beta2    0x00903002 (same as ...beta2-dev)
 * 0.9.3          0x0090300f
 * 0.9.3a         0x0090301f
 * 0.9.4          0x0090400f
 * 1.2.3z         0x102031af
 *
 * For continuity reasons (because 0.9.5 is already out, and is coded
 * 0x00905100), between 0.9.5 and 0.9.6 the coding of the patch level
 * part is slightly different, by setting the highest bit.  This means
 * that 0.9.5a looks like this: 0x0090581f.  At 0.9.6, we can start
 * with 0x0090600S...
 *
 * (Prior to 0.9.3-dev a different scheme was used: 0.9.2b is 0x0922.)
 * (Prior to 0.9.5a beta1, a different scheme was used: MMNNFFRBB for
 *  major minor fix final patch/beta)
 */
#define OPENSSL_VERSION_NUMBER  0x1000109fL

#define OPENSSL_VERSION_PTEXT   " part of " OPENSSL_VERSION_TEXT

/* The macros below are to be used for shared library (.so, .dll, ...)
 * versioning.  That kind of versioning works a bit differently between
 * operating systems.  The most usual scheme is to set a major and a minor
 * number, and have the runtime loader check that the major number is equal
 * to what it was at application link time, while the minor number has to
 * be greater or equal to what it was at application link time.  With this
 * scheme, the version number is usually part of the file name, like this:
 *
 *      libcrypto.so.0.9
 *
 * Some unixen also make a softlink with the major verson number only:
 *
 *      libcrypto.so.0
 *
 * On Tru64 and IRIX 6.x it works a little bit differently.  There, the
 * shared library version is stored in the file, and is actually a series
 * of versions, separated by colons.  The rightmost version present in the
 * library when linking an application is stored in the application to be
 * matched at run time.  When the application is run, a check is done to
 * see if the library version stored in the application matches any of the
 * versions in the version string of the library itself.
 * This version string can be constructed in any way, depending on what
 * kind of matching is desired.  However, to implement the same scheme as
 * the one used in the other unixen, all compatible versions, from lowest
 * to highest, should be part of the string.  Consecutive builds would
```

```
 * give the following versions strings:
 *
 *      3.0
 *      3.0:3.1
 *      3.0:3.1:3.2
 *      4.0
 *      4.0:4.1
 *
 * Notice how version 4 is completely incompatible with version, and
 * therefore give the breach you can see.
 *
 * There may be other schemes as well that I haven't yet discovered.
 *
 * So, here's the way it works here: first of all, the library version
 * number doesn't need at all to match the overall OpenSSL version.
 * However, it's nice and more understandable if it actually does.
 * The current library version is stored in the macro SHLIB_VERSION_NUMBER,
 * which is just a piece of text in the format "M.m.e" (Major, minor, edit).
 * For the sake of Tru64, IRIX, and any other OS that behaves in similar ways,
 * we need to keep a history of version numbers, which is done in the
 * macro SHLIB_VERSION_HISTORY.  The numbers are separated by colons and
 * should only keep the versions that are binary compatible with the current.
 */
#define SHLIB_VERSION_HISTORY ""
#define SHLIB_VERSION_NUMBER "1.0.0"
