#
# Adjunct for building things that run on the build machine.
#
NATIVE_ADJUNCT= /usr

#
# RELEASE_BUILD should be cleared for final release builds.
# NOT_RELEASE_BUILD is exactly what the name implies.
#
# __GNUC toggles the building of ON components using gcc and related tools.
# Normally set to '#', set it to '' to do gcc build.
#
# The declaration POUND_SIGN is always '#'. This is needed to get around the
# make feature that '#' is always a comment delimiter, even when escaped or
# quoted. We use this macro expansion method to get POUND_SIGN rather than
# always breaking out a shell because the general case can cause a noticable
```

```
# slowdown in build times when so many Makefiles include Makefile.master.
#
# While the majority of users are expected to override the setting below
# with an env file (via nightly or bldenv), if you aren't building that way
# (ie, you're using "ws" or some other bootstrapping method) then you need
# this definition in order to avoid the subshell invocation mentioned above.
#

# The variables below control the compilers used during the build.
# There are a number of permutations.
#
# __GNUC and __SUNC control (and indicate) the primary compiler.  Whichever
# one is not POUND_SIGN is the primary, with the other as the shadow.  They
# may also be used to control entirely compiler-specific Makefile assignments.
# __GNUC and GCC are the default.
#
# __GNUC64 indicates that the 64bit build should use the GNU C compiler.
# There is no Sun C analogue.
#
# The following version-specific options are operative regardless of which
# compiler is primary, and control the versions of the given compilers to be
# used.  They also allow compiler-version specific Makefile fragments.
#

__SUNC=                 $(POUND_SIGN)
$(__SUNC)__GNUC=        $(POUND_SIGN)
__GNUC64=               $(__GNUC)

# Allow build-time "configuration" to enable or disable some things.
# The default is POUND_SIGN, meaning "not enabled". If the environment
# passes in an override like ENABLE_SMB_PRINTING= (empty) that will
# uncomment things in the lower Makefiles to enable the feature.

# With studio CSTD of neither enabled nor disabled is "no_lib", whereby we
# expect C99-the-language, but don't modify the behaviour of library routines.
# This is VERY IMPORTANT, as $(CSTD_GNU99), for instance, would link us with
# values-xpg6, which would introduce an __xpg6 to our object with the C99
# flags set, causing us to default C99 libm behaviour on, breaking
# compatibility.
#
# We must then, unfortunately, defeat the GNU compiler _defaulting_ to C99, by
# in that case setting it back to gnu89, which _also_ accepts C99 syntax as
# far as is important.

# Bootstrap problem: 'cw' must be built before anything else can be built.
# 'install.bin' should be built next, being the 'install' target dependency
# for everything else.
#
# Because of somewhat cyclic dependency between them, both cw and install.bin
# override the way we install binaries in their Makefiles.

/*
 * -#           Verbose mode
 * -###         Show compiler commands built by driver, no compilation
 * -A<name[(tokens)]>   Preprocessor predicate assertion
 * -B<[static|dynamic]> Specify dynamic or static binding
 * -C           Prevent preprocessor from removing comments
 * -c           Compile only - produce .o files, suppress linking
 * -cg92        Alias for -xtarget=ss1000
 * -D<name[=token]>     Associate name with token as if by #define
 * -d[y|n]      dynamic [-dy] or static [-dn] option to linker
 * -E           Compile source through preprocessor only, output to stdout
 * -erroff=<t>  Suppress warnings specified by tags t(%none, %all, <tag list>)
 * -errtags=<a> Display messages with tags a(no, yes)
 * -errwarn=<t> Treats warnings specified by tags t(%none, %all, <tag list>)
 *              as errors
 * -fast        Optimize using a selection of options
 * -fd          Report old-style function definitions and declarations
```

```
 * -fnonstd     Initialize floating-point hardware to non-standard preferences
 * -fns[=<yes|no>] Select non-standard floating point mode
 * -fprecision=<p> Set FP rounding precision mode p(single, double, extended)
 * -fround=<r>  Select the IEEE rounding mode in effect at startup
 * -fsimple[=<n>] Select floating-point optimization preferences <n>
 * -fsingle     Use single-precision arithmetic (-Xt and -Xs modes only)
 * -ftrap=<t>   Select floating-point trapping mode in effect at startup
 * -fstore      force floating pt. values to target precision on assignment
 * -G           Build a dynamic shared library
 * -g           Compile for debugging
 * -H           Print path name of each file included during compilation
 * -h <name>    Assign <name> to generated dynamic shared library
 * -I<dir>      Add <dir> to preprocessor #include file search path
 * -i           Passed to linker to ignore any LD_LIBRARY_PATH setting
 * -keeptmp     Keep temporary files created during compilation
 * -L<dir>      Pass to linker to add <dir> to the library search path
 * -l<name>     Link with library lib<name>.a or lib<name>.so
 * -mc          Remove duplicate strings from .comment section of output files
 * -mr          Remove all strings from .comment section of output files
 * -mr,"string" Remove all strings and append "string" to .comment section
 * -mt          Specify options needed when compiling multi-threaded code
 * -native      Find available processor, generate code accordingly
 * -nofstore    Do not force floating pt. values to target precision
 *              on assignment
 * -norunpath   Do not build in a runtime path for shared libraries
 * -O           Use default optimization level (-xO2 or -xO3. Check man page.)
 * -o <outputfile> Set name of output file to <outputfile>
 * -P           Compile source through preprocessor only, output to .i  file
 * -p           Compile for profiling with prof
 * -Q[y|n]      Emit/don't emit identification info to output file
 * -R<dir[:dir]> Build runtime search path list into executable
 * -S           Compile and only generate assembly code (.s)
 * -s           Strip symbol table from the executable file
 * -t           Turn off duplicate symbol warnings when linking
 * -U<name>     Delete initial definition of preprocessor symbol <name>
 * -V           Report version number of each compilation phase
 * -v           Do stricter semantic checking
 * -W<c>,<arg>  Pass <arg> to specified component <c> (a,l,m,p,0,2,h,i,u)
 * -w           Suppress compiler warning messages
 * -Xa          Compile assuming ANSI C conformance, allow K & R extensions
 *              (default mode)
 * -Xs          Compile assuming (pre-ANSI) K & R C style code
 * -Xt          Compile assuming K & R conformance, allow ANSI C
 * -xarch=<a>   Specify target architecture instruction set
 * -xbuiltin[=<b>] When profitable inline, or substitute intrinisic functions
 *              for system functions, b={%all,%none}
 * -xCC         Accept C++ style comments
 * -xchip=<c>   Specify the target processor for use by the optimizer
 * -xcode=<c>   Generate different code for forming addresses
 * -xcrossfile[=<n>] Enable optimization and inlining across source files,
 *              n={0|1}
 * -xe          Perform only syntax/semantic checking, no code generation
 * -xF          Compile for later mapfile reordering or unused section
 *              elimination
 * -xhelp=<f>   Display on-line help information f(flags, readme, errors)
 * -xildoff     Cancel -xildon
 * -xildon      Enable use of the incremental linker, ild
 * -xinline=[<a>,...,<a>]  Attempt inlining of specified user routines,
 *              <a>={%auto,func,no%func}
 * -xlibmieee   Force IEEE 754 return values for math routines in
 *              exceptional cases
 * -xlibmil     Inline selected libm math routines for optimization
 * -xlic_lib=sunperf    Link in the Sun supplied performance libraries
 * -xlicinfo    Show license server information
 * -xmaxopt=[off,1,2,3,4,5] maximum optimization level allowed on #pragma opt
 * -xO<n>       Generate optimized code (n={1|2|3|4|5})
```

```
 * -xP          Print prototypes for function definitions
 * -xprofile=<p> Collect data for a profile or use a profile to optimize
 *              <p>={{collect,use}[:<path>],tcov}
 * -xregs=<r>   Control register allocation
 * -xs          Allow debugging without object (.o) files
 * -xsb         Compile for use with the WorkShop source browser
 * -xsbfast     Generate only WorkShop source browser info, no compilation
 * -xsfpconst   Represent unsuffixed floating point constants as single
 *              precision
 * -xspace      Do not do optimizations that increase code size
 * -xstrconst   Place string literals into read-only data segment
 * -xtarget=<t> Specify target system for optimization
 * -xtemp=<dir> Set directory for temporary files to <dir>
 * -xtime       Report the execution time for each compilation phase
 * -xunroll=n   Enable unrolling loops n times where possible
 * -Y<c>,<dir>  Specify <dir> for location of component <c> (a,l,m,p,0,h,i,u)
 * -YA,<dir>    Change default directory searched for components
 * -YI,<dir>    Change default directory searched for include files
 * -YP,<dir>    Change default directory for finding libraries files
 * -YS,<dir>    Change default directory for startup object files

# PRIMARY_CC    - primary C compiler
# PRIMARY_CCC   - primary C++ compiler
#
# SHADOW_CCS    - list of shadow C compilers
# SHADOW_CCCS   - list of shadow C++ compilers
#
```

```
# Each entry has the form <name>,<path to binary>,<style> where name is a
# free-form name (possibly used in the makefiles to guard options), path is
# the path to the executable.  style is the 'style' of command line taken by
# the compiler, currently either gnu (or gcc) or sun (or cc), which is also
# used by Makefiles to guard options.
#
# __SUNC and __GNUC must still be set to reflect the style of the primary
# compiler (and to influence the default primary, otherwise)
#
# for example:
# export PRIMARY_CC=gcc4,/opt/gcc/4.4.4/bin/gcc,gnu
# export PRIMARY_CCC=gcc4,/opt/gcc/4.4.4/bin/g++,gnu
# export SHADOW_CCS=studio12,/opt/SUNWspro/bin/cc,sun
# export SHADOW_CCCS=studio12,/opt/SUNWspro/bin/CC,sun
#
# There can be several space-separated entries in SHADOW_* to run multiple
# shadow compilers.
#
# To disable shadow compilation, unset SHADOW_* or set them to the empty string.
#
export SHADOW_CCS=gcc7,/usr/gcc/7/bin/gcc,gnu
export SHADOW_CCCS=gcc7,/usr/gcc/7/bin/g++,gnu

# Two entries in the findunref exception_list deal with things created
# by nightly.  Otherwise, this test could be run on an unmodifed (and
# unbuilt) workspace.  We handle this by flagging the one that is
# present only on a built workspace (./*.out) and the one that's
# present only after a run of findunref (./*.ref) with ISUSED, and
# disabling all checks of them.  The assumption is that the entries
# marked with ISUSED are always known to be good, thus the Latin quote
# at the top of the file.
#
# The exception_list is generated from whichever input files are appropriate
# for this workspace, so checking it obviates the need to check the inputs.

10063 basic support for smatch
10153 checkpaths shouldn't check packaging exceptions
**********

```
- A slightly edited irc discussion with Josh Triplett.
- Describes most data structures used in sparse.

As far as the parsing structures go...
The C parser exists in two main files: parse.c, which parses statements, and exp
parse.h contains the definition of struct statement, which represents a C statem
That includes only those things which can't appear as an expression, which prima
expression.h contains the definition of struct expression, which represents a C
A series of statements forms a compound statement (STMT_COMPOUND).
That appears as another struct statement which has a statement_list member.
A function body consists of a compound statement.
When you look at a loop body, if or else body, or case body, you'll notice that
Also note that all loops get turned into a single "iterator" statement.
for, while, and do-while.
A symbol, then, represents a name in a C file.  A symbol might represent a varia
See symbol.h.
"struct symbol" represents one symbol.
As with the various other structures, it has some common data and a union of sub
Most of the interesting bits come in the NS_SYMBOL case.
Among other things, it has a struct statement for the body of a function (if any
Together, struct symbol, struct statement, and struct expression represent most
So, that represents most of the "front-end" of Sparse: parsing C and generating
That much occurs in pretty much any program using the Sparse frontend.
The backend varies among programs.
For instance, the c2xml backend goes that far, then outputs XML.
The sparse static analysis backend has a few steps: it generates linearized byte
Several other backends run that linearized bytecode stage.
The linearized bytecode itself has a set of nested structures.
linearize.h defines all of them.
At the top level, it has struct entrypoint.
That represents an entrypoint to the code, which would normally mean a function.
An entrypoint has a list of basic blocks.
struct basic_block.
A basic block represents a series of instructions with no branches.
Straight-line code.
A branch only occurs at the end of a basic block, and branches can only target t
Typically, a conditional will consist of a basic block leading up to the branch,
Either the true or the false case may not exist.
A loop will normally have a basic block for the loop body, which can branch to t
So basic blocks represent a node in the control flow graph.
The edges in that graph lead from one basic block to a basic block which can fol
Each basic block has a series of instructions, "struct instruction".
"enum opcode" lists all the instructions.
Fairly high-level instruction set, corresponding directly to bits of C.
So you have an entrypoint, which has a graph of basic blocks, each of which has
An entrypoint also has a pointer to the first instruction.
One last bit of trickiness: struct pseudo.
Have you ever heard of "static single assignment" or SSA form?
struct pseudo represents one of those single-assignment variables.
Each one has a pointer to the symbol it represents (which may have many pseudos
Each one also has a pointer to the instruction that defines it.
That covers most of the major data structures in Sparse.
Now, given all that, some of the top-level stuff in sparse.c may make more sense
For instance, the context checking works in terms of basic blocks.
Hopefully some of that helped you understand Sparse better.
```

Why hacking on sparse
=====================

1. sparse is small.
   The full project compiles in less than 10 seconds on old and not performing l
2. sparse is fast.
   Typically, sparse can check a C file 1/10 of time it takes for gcc to generat
3. sparse can digest the full kernel source files.
   With sparse-llvm, sparse uses llvm as back end to emit real machine code.

New developer hacking on sparse
===============================

* All sparse warning messages should include the option how
   to disable it.
       e.g. "pre-process.c:20*:28: warning: Variable length array is used."
       should be something like
        "pre-process.c:20*:28: warning: Variable length array is
used. (-Wno-vla)"
* extend test-inspect to inspect more AST fields.
* extend test-inspect to inspect instructions.
* adding architecture handling in sparse similar to cgcc
* parallel processing of test-suite
* Howto: fix the kernel rcu related checker warnings
* option to disable AST level inline.
* debug: debug version of sparse do all the verification double check
* test suite: verify and compare IR (suggested by Dibyendu Majumdar)
* checker error output database

For experienced developers
==========================

* merge C type on incremental declare of C type and function prototype.
* move attribute out of ctype to allow easier to add new attribute.
* serialize, general object walking driven by data structures.
* serialize, write sparse byte code into file
* serialize, load sparse byte code from file.
* symbol index/linker, know which symbol in which byte code file.
* inline function in instruction level
* cross function checking
* debug: optimization step by step log
* debug: fancy animation of CFG
* phi node location (Luc has patch)
* revisit crazy programmer warning, invalid SSA form.
* ptrlist, looping while modify inside the loop.
* dead code elimination using ssa
* constant propagation using ssa.
* x86/arm back end instruction set define
* register allocation.
* emit x86/arm machine level code
```

```

Smatch

1.  Building Smatch
2.  Using Smatch
3.  Smatch vs Sparse

Section 1:  Building Smatch
---------------------------

Smatch requires sqlite3.  It requires the binaries and the C, Perl and
Python libraries for sqlite3.

apt-get install sqlite3 libsqlite3-dev libdbd-sqlite3-perl

Smatch is easy to build.  Just type 'make'.  There isn't an install process
right now so just run it from the build directory.

Section 2:  Using Smatch
------------------------

Smatch can be used with a cross function database. It's not mandatory to
build the database but it's a useful thing to do.  Building the database
for the kernel takes 2-3 hours on my computer.  For the kernel you build
the database with:

        cd ~/path/to/kernel_dir
        ~/path/to/smatch_dir/smatch_scripts/build_kernel_data.sh

For projects other than the kernel you run Smatch with the options
"--call-tree --info --param-mapper --spammy" and finish building the
database by running the script:

        ~/progs/smatch/devel/smatch_data/db/create_db.sh

Each time you rebuild the cross function database it becomes more accurate. I
normally rebuild the database every morning.

If you are running Smatch over the whole kernel you can use the following
command:

        ~/progs/smatch/devel/smatch_scripts/test_kernel.sh

The test_kernel.sh script will create a .c.smatch file for every file it tests
and a combined smatch_warns.txt file with all the warnings.

If you are running Smatch just over one kernel file:

        ~/progs/smatch/devel/smatch_scripts/kchecker drivers/whatever/file.c

You can also build a directory like this:

        ~/progs/smatch/devel/smatch_scripts/kchecker drivers/whatever/

The kchecker script prints its warnings to stdout.

If you are building something else (which is not the Linux kernel) then use
something like:
```

```
        make CHECK="~/progs/smatch/devel/smatch --full-path" \
                CC=~/progs/smatch/devel/smatch/cgcc | tee smatch_warns.txt

The makefile has to let people set the CC with an environment variable for that
to work, of course.

Section 3:  Smatch vs Sparse
----------------------------

Smatch uses Sparse as a C parser.  I have made a few hacks to Sparse so I
have to distribute the two together.  Sparse is released under the MIT license
and Smatch is GPLv2+.  If you make changes to Sparse please send those to the
Sparse mailing list linux-sparse@vger.kernel.org and I will pick them up from
there.  Partly I do that for licensing reasons because I don't want to pull GPL
changes into the Sparse code I re-distribute.
```

```

**********************************************************

  sparse (spˆ/rs), adj,., spars-er, spars-est.
        1. thinly scattered or distributed; "a sparse population"
        2. thin; not thick or dense: "sparse hair"
        3. scanty; meager.
        4. semantic parse
        [ from Latin: spars(us) scattered, past participle of
          spargere 'to sparge' ]

        Antonym: abundant

Sparse is a semantic parser of source files: it's neither a compiler
(although it could be used as a front-end for one) nor is it a
preprocessor (although it contains as a part of it a preprocessing
phase).

It is meant to be a small - and simple - library.  Scanty and meager,
and partly because of that easy to use.  It has one mission in life:
create a semantic parse tree for some arbitrary user for further
analysis.  It's not a tokenizer, nor is it some generic context-free
parser.  In fact, context (semantics) is what it's all about - figuring
out not just what the grouping of tokens are, but what the _types_ are
that the grouping implies.

And no, it doesn't use lex and yacc (or flex and bison).  In my personal
opinion, the result of using lex/yacc tends to end up just having to
fight the assumptions the tools make.

The parsing is done in five phases:

 - full-file tokenization
 - pre-processing (which can cause another tokenization phase of another
   file)
 - semantic parsing.
 - lazy type evaluation
 - inline function expansion and tree simplification

Note the "full file" part. Partly for efficiency, but mostly for ease of
use, there are no "partial results". The library completely parses one
whole source file, and builds up the _complete_ parse tree in memory.

Also note the "lazy" in the type evaluation.  The semantic parsing
itself will know which symbols are typedefines (required for parsing C
correctly), but it will not have calculated what the details of the
different types are.  That will be done only on demand, as the back-end
requires the information.

This means that a user of the library will literally just need to do

  struct string_list *filelist = NULL;
  char *file;

  action(sparse_initialize(argc, argv, filelist));

  FOR_EACH_PTR_NOTAG(filelist, file) {
    action(sparse(file));
  } END_FOR_EACH_PTR_NOTAG(file);

and he is now done - having a full C parse of the file he opened.  The
library doesn't need any more setup, and once done does not impose any
```

```
more requirements.  The user is free to do whatever he wants with the
parse tree that got built up, and needs not worry about the library ever
again.  There is no extra state, there are no parser callbacks, there is
only the parse tree that is described by the header files. The action
funtion takes a pointer to a symbol_list and does whatever it likes with it.

The library also contains (as an example user) a few clients that do the
preprocessing, parsing and type evaluation and just print out the
results.  These clients were done to verify and debug the library, and
also as trivial examples of what you can do with the parse tree once it
is formed, so that users can see how the tree is organized.
```

Sparse
~~~~~~

__nocast vs __bitwise:

__nocast warns about explicit or implicit casting to different types.

HOWEVER, it doesn't consider two 32-bit integers to be different
types, so a __nocast 'int' type may be returned as a regular 'int'
type and then the __nocast is lost.

So "__nocast" on integer types is usually not that powerful. It just
gets lost too easily. It's more useful for things like pointers. It
also doesn't warn about the mixing: you can add integers to __nocast
integer types, and it's not really considered anything wrong.

__bitwise ends up being a "stronger integer separation". That one
doesn't allow you to mix with non-bitwise integers, so now it's much
harder to lose the type by mistake.

So the basic rule is:

 - "__nocast" on its own tends to be more useful for *big* integers
that still need to act like integers, but you want to make it much
less likely that they get truncated by mistake. So a 64-bit integer
that you don't want to mistakenly/silently be returned as "int", for
example. But they mix well with random integer types, so you can add
to them etc without using anything special. However, that mixing also
means that the __nocast really gets lost fairly easily.

 - "__bitwise" is for *unique types* that cannot be mixed with other
types, and that you'd never want to just use as a random integer (the
integer 0 is special, though, and gets silently accepted iirc - it's
kind of like "NULL" for pointers). So "gfp_t" or the "safe endianness"
types would be __bitwise: you can only operate on them by doing
specific operations that know about *that* particular type.

Generally, you want __bitwise if you are looking for type safety.
"__nocast" really is pretty weak.

Reference:

* Linus' e-mail about __nocast vs __bitwise:

  http://marc.info/?l=linux-mm&m=133245421127324&w=2

```
  3         Sparse test suite
  4         ~~~~~~~~~~~~~~~~~

  6 Sparse has a number of test cases in its validation directory. The test-suite
  7 script aims at making automated checking of these tests possible. It works by
  8 embedding tags in C comments in the test cases.

 10 check-name: (mandatory)
 11         Name of the test.

 13 check-description: (optional)
 14         A description of what the test checks.

 16 check-command: (optional)
 17         There are different kinds of tests. Some can validate the sparse
 18         preprocessor, while others will use sparse, cgcc, or even other backends
 19         of the library. check-command allows you to give a custom command to
 20         run the test-case.
 21         The '$file' string is special. It will be expanded to the file name at
 22         run time.
 23         It defaults to "sparse $file".

 25 check-exit-value: (optional)
 26         The expected exit value of check-command. It defaults to 0.

 28 check-timeout: (optional)
 29         The maximum expected duration of check-command, in seconds.
 30         It defaults to 1.

 32 check-output-start / check-output-end (optional)
 33         The expected output (stdout and stderr) of check-command lies between
 34         those two tags. It defaults to no output.

 36 check-output-ignore / check-error-ignore (optional)
 37         Don't check the expected output (stdout or stderr) of check-command
 38         (useful when this output is not comparable or if you're only interested
 39         in the exit value).
 40         By default this check is done.

 42 check-known-to-fail (optional)
 43         Mark the test as being known to fail.

 45 check-output-contains: <pattern> (optional)
 46         Check that the output (stdout) contains the given pattern.
 47         Several such tags can be given, in which case the output
 48         must contains all the patterns.

 50 check-output-excludes: <pattern> (optional)
 51         Similar than the above one, but with opposite logic.
 52         Check that the output (stdout) doesn't contain the given pattern.
 53         Several such tags can be given, in which case the output
 54         must contains none of the patterns.

 56 check-output-pattern-<nbr>-times: <pattern> (optional)
 57         Similar to the contains/excludes above, but with full control
 58         of the number of times the pattern should occur in the output.

 60         Using test-suite
```

```
 61         ~~~~~~~~~~~~~~~~

 63 The test-suite script is called through the check target of the Makefile. It
 64 will try to check every test case it finds (find validation -name '*.c').

 66 It can be called to check a single test with:
 67 $ cd validation
 68 $ ./test-suite single preprocessor/preprocessor1.c
 69      TEST     Preprocessor #1 (preprocessor/preprocessor1.c)
 70 preprocessor/preprocessor1.c passed !

 73         Writing a test
 74         ~~~~~~~~~~~~~~

 76 test-suite comes with a format command to make a test easier to write:

 78         test-suite format file [name [cmd]]

 80 name:
 81         check-name value. If no name is provided, it defaults to the file name.
 82 cmd:
 83         check-command value. If no cmd is provided, it defaults to
 84         "sparse $file".

 86 The output of the test-suite format command can be redirected into the
 87 test case to create a test-suite formatted file.

 89 $ ./test-suite format bad-assignment.c Assignment >> bad-assignment.c
 90 $ cat !$
 91 cat bad-assignment.c
 92 /*
 93  * check-name: bad assignment
 94  *
 95  * check-command: sparse $file
 96  * check-exit-value: 1
 97  *
 98  * check-output-start
 99 bad-assignment.c:3:6: error: Expected ; at end of statement
100 bad-assignment.c:3:6: error: got \
101  * check-output-end
102  */

104 You can define the check-command you want to use for the test. $file will be
105 extended to the file name at run time.

107 $ ./test-suite format validation/preprocessor2.c "Preprocessor #2" \
108                  "sparse -E \$file" >> validation/preprocessor2.c
109 $ cat !$
110 cat validation/preprocessor2.c
111 /*
112  * This one we happen to get right.
113  *
114  * It should result in a simple
115  *
116  *      a + b
117  *
118  * for a proper preprocessor.
119  */
120 #define TWO a, b

122 #define UNARY(x) BINARY(x)
123 #define BINARY(x, y) x + y

125 UNARY(TWO)
126 /*
```

```
 * check-name: Preprocessor #2
 *
 * check-command: sparse -E $file
 * check-exit-value: 0
 *
 * check-output-start

a + b
 * check-output-end
 */
```

```

10153 checkpaths shouldn't check packaging exceptions
**********************************************************
```

```
        FAQ - Why sparse?

Q.  Why not just use gcc?

A.  Gcc is big, complex, and the gcc maintainers are not interested in
    other uses of the gcc front-end.  In fact, gcc has explicitly
    resisted splitting up the front and back ends and having some common
    intermediate language because of religious license issues - you can
    have multiple front ends and back ends, but they all have to be part
    of gcc and licensed under the GPL.

    This all (in my opinion) makes gcc development harder than it should
    be, and makes the end result very ungainly.  With "sparse", the
    front-end is very explicitly separated into its own independent
    project, and is totally independent from the users.  I don't want to
    know what you do in the back-end, because I don't think I _should_
    know or care.

Q.  Why not GPL?

A.  See the previous question: I personally think that the front end
    must be a totally separate project from the back end: any other
    approach just leads to insanity.  However, at the same time clearly
    we cannot write intermediate files etc crud (since then the back end
    would have to re-parse the whole thing and would have to have its
    own front end and just do a lot of things that do not make any sense
    from a technical standpoint).

    I like the GPL, but as rms says, "Linus is just an engineer". I
    refuse to use a license if that license causes bad engineering
    decisions.  I want the front-end to be considered a separate
    project, yet the GPL considers the required linking to make the
    combined thing a derived work. Which is against the whole point
    of 'sparse'.

    I'm not interested in code generation. I'm not interested in what
    other people do with their back-ends.  I _am_ interested in making a
    good front-end, and "good" means that people find it usable. And
    they shouldn't be scared away by politics or licenses. If they want
    to make their back-end be BSD/MIT licensed, that's great. And if
    they want to have a proprietary back-end, that's ok by me too. It's
    their loss, not mine.

Q.  Does it really parse C?

A.  Yeah, well...  It parses a fairly complete subset of "extended C" as
    defined by gcc.  HOWEVER, since I don't believe in K&R syntax for
    function declarations or in giving automatic integer types, it
    doesn't do that.  If you don't give types to your variables, they
    won't have any types, and you can't use them.

    Similarly, it will be very unhappy about undeclared functions,
    rather than just assuming they have type "int".

    Note that a large rationale for me doing this project is for type
    following, which to some degree explains why the thing is type-anal
    and refuses to touch the old-style pre-ANSI non-typed (or weakly
    typed) constructs. Maybe somebody else who is working on projects
```

```
    where pre-ANSI C makes sense might be more inclined to care about
    ancient C.  It's open source, after all. Go wild.

Q.  What other sparse resources are available?

A.  Wiki: http://sparse.wiki.kernel.org/index.php/Main_Page

    Mailing list: linux-sparse@vger.kernel.org
    See http://vger.kernel.org/vger-lists.html#linux-sparse for subscription
    instructions and links to archives

    Git repo: git://git.kernel.org/pub/scm/devel/sparse/sparse.git
    gitweb: http://git.kernel.org/?p=devel/sparse/sparse.git
```

# GNU GENERAL PUBLIC LICENSE
## Version 2, June 1991

## Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Lesser General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

## GNU GENERAL PUBLIC LICENSE
## TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

    a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

    b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

    c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or

collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

  3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

    a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

    b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

    c) Accompany it with the information you received as to the offer to distribute corresponding source code.  (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it.  For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable.  However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

  4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License.  Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

  5. You are not required to accept this License, since you have not signed it.  However, nothing else grants you permission to modify or distribute the Program or its derivative works.  These actions are prohibited by law if you do not accept this License.  Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

  6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions.  You may not impose any further

restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

  7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License.  If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all.  For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices.  Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

  8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded.  In such case, this License incorporates the limitation as if written in the body of this License.

  9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time.  Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number.  If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation.  If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

  10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission.  For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this.  Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

                            NO WARRANTY

  11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY
FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW.  EXCEPT WHEN
OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES
PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED
OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF
MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.  THE ENTIRE RISK AS
TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU.  SHOULD THE
PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING,
REPAIR OR CORRECTION.

  12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING
WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR
REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES,
INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING
OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED
TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY
YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER
PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE
POSSIBILITY OF SUCH DAMAGES.

                     END OF TERMS AND CONDITIONS

            How to Apply These Terms to Your New Programs

  If you develop a new program, and you want it to be of the greatest
possible use to the public, the best way to achieve this is to make it
free software which everyone can redistribute and change under these terms.

  To do so, attach the following notices to the program.  It is safest
to attach them to the start of each source file to most effectively
convey the exclusion of warranty; and each file should have at least
the "copyright" line and a pointer to where the full notice is found.

    <one line to give the program's name and a brief idea of what it does.>
    Copyright (C) <year>  <name of author>

    This program is free software; you can redistribute it and/or modify
    it under the terms of the GNU General Public License as published by
    the Free Software Foundation; either version 2 of the License, or
    (at your option) any later version.

    This program is distributed in the hope that it will be useful,
    but WITHOUT ANY WARRANTY; without even the implied warranty of
    MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the
    GNU General Public License for more details.

    You should have received a copy of the GNU General Public License along
    with this program; if not, write to the Free Software Foundation, Inc.,
    51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this
when it starts in an interactive mode:

    Gnomovision version 69, Copyright (C) year name of author
    Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type 'show w'.
    This is free software, and you are welcome to redistribute it
    under certain conditions; type 'show c' for details.

The hypothetical commands 'show w' and 'show c' should show the appropriate
parts of the General Public License.  Of course, the commands you use may
be called something other than 'show w' and 'show c'; they could even be
mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your
school, if any, to sign a "copyright disclaimer" for the program, if
necessary.  Here is a sample; alter the names:

  Yoyodyne, Inc., hereby disclaims all copyright interest in the program
  'Gnomovision' (which makes passes at compilers) written by James Hacker.

  <signature of Ty Coon>, 1 April 1989
  Ty Coon, President of Vice

This General Public License does not permit incorporating your program into
proprietary programs.  If your program is a subroutine library, you may
consider it more useful to permit linking proprietary applications with the
library.  If this is what you want to do, use the GNU Lesser General
Public License instead of this License.

**********************************************************
Smatch is released under the GPLv2+ license however Smatch includes the Sparse
source as well which is licensed under the MIT license and cwchash which is
licensed under the three clause BSD license and avl.[ch] which are MIT licensed.

The line between which files are a part of Sparse and which are a part of Smatch
is normally pretty clear.  The one thing I will clarify is that there are some
modifications to Sparse files in the Smatch repository which have not been
pushed to the Sparse repository.  These are released under the MIT license.  The
token_store.c file is a Sparse feature and thus released under the MIT license
despite that it has not been pushed to the Sparse repository.

I will not accept additional Sparse features except under the MIT license.

 *
 * Simple allocator for data that doesn't get partially free'd.
 * The tokenizer and parser allocate a _lot_ of small data structures
 * (often just two-three bytes for things like small integers),
 * and since they all depend on each other you can't free them
 * individually _anyway_. So do something that is very space-
 * efficient: allocate larger "blobs", and give out individual
 * small bits and pieces of it with no maintenance overhead.

.\" cgcc manpage by Josh Triplett
.TH cgcc "1"
.
.SH NAME
cgcc \- Compiler wrapper to run Sparse after compiling
.
.SH SYNOPSIS
.B cgcc
[\fISPARSE OPTIONS\fR]... [\fICOMPILER OPTIONS\fR]... [\fIINPUT FILES\fR]...
.br
.B make CC=cgcc
.
.SH DESCRIPTION
\fBcgcc\fR provides a wrapper around a C compiler (\fBcc\fR by
default) which also invokes the Sparse static analysis tool.
.P
\fBcgcc\fR accepts all Sparse command-line options, such as warning
options, and passes all other options through to the compiler.
.P
By providing the same interface as the C compiler, \fBcgcc\fR allows
projects to run Sparse as part of their build without modifying their
build system, by using \fBcgcc\fR as the compiler.  For many projects,
setting \fBCC=cgcc\fR on the \fBmake\fR command-line will work.
.
.SH ENVIRONMENT
.TP
.B REAL_CC
If set, \fBcgcc\fR will use this as the compiler to invoke, rather
than the default \fBcc\fR.
.
.TP
.B CHECK
If set, \fBcgcc\fR will use this as the Sparse program to invoke,
rather than the default \fBsparse\fR.
.
.SH SEE ALSO
.BR sparse (1)

/*
 * This is like check_deref_check.c except that it complains about code like:
 * if (a)
 *       a->foo = 42;
 * a->bar = 7;
 *
 * Of course, Smatch has complained about these for forever but the problem is
 * the old scripts were too messy and complicated and generated too many false
 * positives.
 *
 * This check is supposed to be simpler because it only looks for one kind of
 * null dereference bug instead of every kind.  It also gets rid of the false
 * positives caused by the checks that happen inside macros.
 *

/*
 * There was a previous null dereference test but it was too confusing and
 * difficult to debug.  This test is much simpler in its goals and scope.
 *
 * This test only complains about:
 * 1) dereferencing uninitialized variables
 * 2) dereferencing variables which were assigned as null.
 * 3) dereferencing variables which were assigned a function the returns
 *    null.
 *
 * If we dereference something then we complain if any of those three
 * are possible.
 *
 */

/*
 * The point of this check is to look for leaks.
 * foo = malloc();  // <- mark it as allocated.
 * A variable becomes &ok if we:
 * 1) assign it to another variable.
 * 2) pass it to a function.
 *
 * One complication is dealing with stuff like:
 * foo->bar = malloc();
 * foo->baz = malloc();
 * foo = something();
 *
 * The work around is that for now what this check only
 * checks simple expressions and doesn't check whether
 * foo->bar is leaked.
 *

/*
 * First of all, it's best if you lower your expectations from finding
 * errors to just finding suspicious code.  There tends to be a lot
 * of false positives so having low expectations helps.
 *
 * For this test let's look for functions that return a negative value
 * with a semaphore held.
 *
 * This is just a template check.  It's designed for teaching
 * only and is deliberately less useful than it could be.  check_locking.c
 * is a better real world test.
 *
 * The biggest short coming is that it assumes a function isn't supposed
 * to return negative with a lock held.  Also it assumes the function was
 * called without the lock held. It would be better if it handled the stuff
 * like this:
 *     ret = -ENOMEM;
 *     return ret;
 * Another idea would be to test other kinds of locks besides just semaphores.
 *

/*
 * This check is supposed to find places like this:
 * err = foo();
 * err = bar();
 * if (err)
 *         return err;
 * (the first assignment isn't used)
 *
 * How the check works is that every assignment gets an ID.
 * We store that assignment ID in a list of assignments that
 * haven't been used.  We also set the state of 'err' from
 * the example above to be.  Then when we use 'err' we remove
 * it from the list.  At the end of the function we print
 * a list of assignments that still haven't been used.
 *
 * Note that this check only works for assignments to
 * EXPR_SYMBOL.  Maybe it could be modified to cover other
 * assignments later but then you would have to deal with
 * scope issues.
 *
 * Also this state is quite tied to the order the callbacks
 * are called in smatch_flow.c.  (If the order changed it
 * would break).
 *
 */

 *      {    printf("Not found\n");                 }
 *
 */

/* Macros may be used to define type-safe(r) hashtable access functions, with
 * methods specialized to take known key and value types as parameters.
 *
 * Example:
 *
 * Insert this at the start of your file:
 *
 * DEFINE_HASHTABLE_INSERT(insert_some, struct some_key, struct some_value);
 * DEFINE_HASHTABLE_SEARCH(search_some, struct some_key, struct some_value);
 * DEFINE_HASHTABLE_REMOVE(remove_some, struct some_key, struct some_value);
 *
 * This defines the functions 'insert_some', 'search_some' and 'remove_some'.
 * These operate just like hashtable_insert etc., with the same parameters,
 * but their function signatures have 'struct some_key *' rather than
 * 'void *', and hence can generate compile time errors if your program is
 * supplying incorrect data as a key (and similarly for value).
 *
 * Note that the hash and key equality functions passed to create_hashtable
 * still take 'void *' parameters instead of 'some key *'. This shouldn't be
 * a difficult issue as they're only defined and passed once, and the other
 * functions will ensure that only valid keys are supplied to them.
 *
 * The cost for this checking is increased code size and runtime overhead
 * - if performance is important, it may be worth switching back to the
 * unsafe methods once your program has been debugged with the safe methods.
 * This just requires switching to some simple alternative defines - eg:
 * #define insert_some hashtable_insert
```

```
 *
 */

/*****************************************************************************
 * create_hashtable

 * @name                    create_hashtable
 * @param   minsize         minimum initial size of hashtable
 * @param   hashfunction    function for hashing keys
 * @param   key_eq_fn       function for determining key equality
 * @return                  newly created hashtable or NULL on failure
 */
