  70 #define ACPI_ASCII_MAX                  0x7F

  73 /*
  74  * Architecture-specific ACPICA Subsystem Data Types
  75  *
  76  * The goal of these types is to provide source code portability across
  77  * 16-bit, 32-bit, and 64-bit targets.
  78  *
  79  * 1) The following types are of fixed size for all targets (16/32/64):
  80  *
  81  * BOOLEAN      Logical boolean
  82  *
  83  * UINT8        8-bit  (1 byte) unsigned value
  84  * UINT16       16-bit (2 byte) unsigned value
  85  * UINT32       32-bit (4 byte) unsigned value
  86  * UINT64       64-bit (8 byte) unsigned value
  87  *
  88  * INT16        16-bit (2 byte) signed value
  89  * INT32        32-bit (4 byte) signed value
  90  * INT64        64-bit (8 byte) signed value
  91  *
  92  * COMPILER_DEPENDENT_UINT64/INT64 - These types are defined in the
  93  * compiler-dependent header(s) and were introduced because there is no common
  94  * 64-bit integer type across the various compilation models, as shown in
  95  * the table below.
  96  *
  97  * Datatype  LP64 ILP64 LLP64 ILP32 LP32 16bit
  98  * char      8    8     8     8     8    8
  99  * short     16   16    16    16    16   16
 100  * _int32          32
 101  * int       32   64    32    32    16   16
 102  * long      64   64    32    32    32   32
 103  * long long            64    64
 104  * pointer   64   64    64    32    32   32
 105  *
 106  * Note: ILP64 and LP32 are currently not supported.
 107  *
 108  *
 109  * 2) These types represent the native word size of the target mode of the
 110  * processor, and may be 16-bit, 32-bit, or 64-bit as required. They are
 111  * usually used for memory allocation, efficient loop counters, and array
 112  * indexes. The types are similar to the size_t type in the C library and are
 113  * required because there is no C type that consistently represents the native
 114  * data width. ACPI_SIZE is needed because there is no guarantee that a
 115  * kernel-level C library is present.
 116  *
 117  * ACPI_SIZE        16/32/64-bit unsigned value
 118  * ACPI_NATIVE_INT  16/32/64-bit signed value
 119  */

/*
 *      Power Button Driver
 *
 *      This driver handles interrupt generated by the power button on
 *      platforms with "power" device node which has "button" property.
 *      Currently, these platforms are:
 *
 *              ACPI-enabled x86/x64 platforms
 *              Ultra-5_10, Ultra-80, Sun-Blade-100, Sun-Blade-150,
 *              Sun-Blade-1500, Sun-Blade-2500,
 *              Sun-Fire-V210, Sun-Fire-V240, Netra-240
 *
 *      Only one instance is allowed to attach.  In order to know when
 *      an application that has opened the device is going away, a new
 *      minor clone is created for each open(9E) request.  There are
 *      allocations for creating minor clones between 1 and 255.  The ioctl
 *      interface is defined by pbio(7I) and approved as part of
 *      PSARC/1999/393 case.

/*
 * There are three types of container objects defined in the ACPI Spec as below.
 * PNP0A05: Generic Container Device
 *   A device whose settings are totally controlled by its ACPI resource
 *   information, and otherwise needs no device or bus-specific driver support.
 *   This was originally known as Generic ISA Bus Device.
 *   This ID should only be used for containers that do not produce resources
 *   for consumption by child devices. Any system resources claimed by a PNP0A05
 *   device's _CRS object must be consumed by the container itself.
 * PNP0A06: Generic Container Device
 *   This device behaves exactly the same as the PNP0A05 device.
 *   This was originally known as Extended I/O Bus.
 *   This ID should only be used for containers that do not produce resources
 *   for consumption by child devices. Any system resources claimed by a PNP0A06
 *   device's _CRS object must be consumed by the container itself.
 * ACPI0004: Module Device.
 *   This device is a container object that acts as a bus node in a namespace.
 *   A Module Device without any of the _CRS, _PRS and _SRS methods behaves
 *   the same way as the Generic Container Devices (PNP0A05 or PNP0A06).
 *   If the Module Device contains a _CRS method, only the resources
 *   described in the _CRS are available for consumption by its child devices.
 *   Also, the Module Device can support _PRS and _SRS methods if _CRS is
 *   supported.

/*
 * Platform specific device enumerator for ACPI specific devices.
 * "x86 system devices" refers to the suite of hardware components which are
 * common to the x86 platform and play important roles in the system
 * architecture but can't be enumerated/discovered through industry-standard
 * bus specifications. Examples of these x86 system devices include:
 *   * Logical processor/CPU
 *   * Memory device
 *   * Non-PCI discoverable IOMMU or DMA Remapping Engine
 *   * Non-PCI discoverable IOxAPIC
 *   * Non-PCI discoverable HPET (High Precision Event Timer)
 *   * ACPI defined devices, including power button, sleep button, battery etc.
 *
 * X86 system devices may be discovered through BIOS/Firmware interfaces, such
 * as SMBIOS tables, MPS tables and ACPI tables since their discovery isn't
 * covered by any industry-standard bus specifications.
 *
 * In order to aid Solaris in flexibly managing x86 system devices,
 * x86 system devices are placed into a specific firmware device
 * subtree whose device path is '/devices/fw'.
 *
 * This driver populates the firmware device subtree with ACPI-discoverable
 * system devices if possible. To achieve that, the ACPI object
 * namespace is abstracted as ACPI virtual buses which host system devices.
 * Another nexus driver for the ACPI virtual bus will manage all devices
 * connected to it.
 *
 * For more detailed information, please refer to PSARC/2009/104.

/*
 * Solaris uses an HPET Timer to generate interrupts for CPUs in Deep C-state
 * with stalled LAPIC Timers.  All CPUs use one HPET timer.  The timer's
 * interrupt targets one CPU (via the I/O APIC).  The one CPU that receives
 * the HPET's interrupt wakes up other CPUs as needed during the HPET Interrupt
 * Service Routing.  The HPET ISR uses poke_cpus to wake up other CPUs with an
 * Inter Processor Interrupt.
 *
 * Please see the Intel Programmer's guides.  Interrupts are disabled before
 * a CPU Halts into Deep C-state.  (This allows CPU-hardware-specific cleanup
 * before servicing interrupts.)  When a Deep C-state CPU wakes up (due to
 * an externally generated interrupt), it resume execution where it halted.
 * The CPU returning from Deep C-state must enable interrupts before it will
 * handle the pending interrupt that woke it from Deep C-state.
 *
 *
 * HPET bits as defined in the Intel IA-PC HPET Specification Rev 1.0a.
 *
 * The physical address space layout of the memory mapped HPET looks like this:
 *
 * struct hpet {
 *      uint64_t        gen_cap;
```

```
 *      uint64_t        res1;
 *      uint64_t        gen_config;
 *      uint64_t        res2;
 *      uint64_t        gen_inter_stat;
 *      uint64_t        res3;
 *      uint64_t        main_counter_value;
 *      uint64_t        res4;
 *      stuct hpet_timer {
 *              uint64_t        config_and_capability;
 *              uint64_t        comparator_value;
 *              uint64_t        FSB_interrupt_route;
 *              uint64_t        reserved;
 *      } timers[32];
 * }
 *
 * There are 32 possible timers in an hpet.  Only the first 3 timers are
 * required.  The other 29 timers are optional.
 *
 * HPETs can have 64-bit or 32-bit timers.  Timers/compare registers can
 * be 64-bit or 32-bit and can be a mixture of both.
 * The first two timers are not used.  The HPET spec intends the first two
 * timers to be used as "legacy replacement" for the PIT and RTC timers.
 *
 * Solaris uses the first available non-legacy replacement timer as a proxy
 * timer for processor Local APIC Timers that stop in deep idle C-states.
 */

#
#       This Makefile defines all file modules and build rules for the
# directory uts/intel and its children. These are the source files which
# are specific to the intel processor.
#
#       The following two-level ordering must be maintained in this file.
#         Lines are sorted first in order of decreasing specificity based on
#         the first directory component.  That is, sun4u rules come before
#         sparc rules come before common rules.
#
#         Lines whose initial directory components are equal are sorted
#         alphabetically by the remaining components.

#
# Need a way to distinguish between the ia32 and amd64 subdirs.
