 *
 * FUNCTION:    DtGetNextLine
 *
 * PARAMETERS:  Handle              - Open file handle for the source file
 *
 * RETURN:      Filled line buffer and offset of start-of-line (ASL_EOF on EOF)
 *
 * DESCRIPTION: Get the next valid source line. Removes all comments.
 *              Ignores empty lines.
 *
 * Handles both slash-asterisk and slash-slash comments.
 * Also, quoted strings, but no escapes within.
 *
 * Line is returned in Gbl_CurrentLineBuffer.
 * Line number in original file is returned in Gbl_CurrentLineNumber.
 *
 ******************************************************************************/

```

How to add a new ACPI table to ACPICA and the iASL compiler.

There are four main tasks that are needed to provide support for a
new ACPI table:
    1) Create a full definition of the table and any subtables
       in the ACPICA headers.
    2) Add disassembler support for the new table
    3) Add iASL table compiler support for the new table
    4) Create a default template for the new table for iASL -T
       option.

Notes for each of these tasks provided below.

1) Header Support

New tables should be added to the appropriate header:
    actbl2.h: Used for new tables that are not defined in the ACPI spec.
    actbl3.h: Used for new tables that are defined in the ACPI spec.

Use ACPI_TABLE_HEADER for the common ACPI table header.
Subtables should be defined separately from the main table.
Don't add placeholder fields for subtables and other multiple data items.
    (Don't use xxxxx[1] for a field that can have multiple items.)
    The disassembler and data table compiler depends on this.
For tables not defined in the ACPI spec, add a comment to indicate where
    the table came from.
Use other table definitions for additional guidance.

2) iASL Disassembler Support

Add definition of the table (and subtables) in common/dmtbinfo.c
Add table access macro(s) of the form ACPI_xxxx_OFFSET
Add ACPI_DMT_TERMINATOR at the end of every table/subtable definition

Add externals for the table/subtable definitions in acdisasm.h
Add an entry for the new table in the AcpiDmTableData in common/dmtable.c

If there are no subtables, add the AcpiDmTableInfoXXXX name to the
    AcpiDmTableData and it will automatically be disassembled.

If there are subtables, a dump routine must be written:
Add an AcpiDmDumpXXXX function to dmtbdump.c -- note, code for another
    similar table can often be ported for the new table.
Add an external for this function to acdisasm.h
Add this function to the AcpiDmTableData entry for the new ACPI table

Debug/Test: Either find an existing example of the new ACPI table, or
    create one using the "generic ACPI table support" included in the
    iASL data table compiler. Use the -G option to force a
    generic compile. It is often best to create the table from scratch,
    since this clearly exposes the dependencies (lengths, offsets, etc.)
    that the Table Compiler support will need to generate.

3) iASL Table Compiler Support

Simple tables do not require a compile routine. The definition of the
    table in common/dmtbinfo.c (created in step 2 above) will suffice.

Complex tables with subtables will require a compile routine with a name
    of the form DtCompileXXXX.
Add a DtCompileXXXX function to the dttable.c module.
Add an external for this function in dtcompiler.h
Add this function to the AcpiDmTableData entry for the new ACPI table
    in common/dmtable.c

4) Template Support (-T iASL option)

Create an example of the new ACPI table. This example should create
    multiple subtables (if supported), and multiple instances of any
    variable length data.

Compile the example file with the -sc option. This will create a C
    array that contains the table contents.

Add this array to the dttemplate.h file. Name the array TemplateXXXX.
Add this array name to the AcpiDmTableData entry for the new ACPI table

Debug/Test: Create the template file. Compile the file. Disassemble the file.
    Compile the disassembly file.

/*
 * Miscellaneous instructions for building and using the iASL compiler.
 */
Last update 9 December 2013.

1) Generating iASL from source
------------------------------

Generation of the ASL compiler from source code requires these items:

    1) The ACPICA source code tree.
    2) An ANSI C compiler.
    3) The Flex (or Lex) lexical analyzer generator.
    4) The Bison (or Yacc) parser generator.

There are three major ACPICA source code components that are required to
generate the compiler (Basically, the entire ACPICA source tree should
be installed):

    1) The ASL compiler source.
    2) The ACPICA Core Subsystem source. In particular, the Namespace
       Manager component is used to create an internal ACPI namespace
       and symbol table, and the AML Interpreter is used to evaluate
       constant expressions.
    3) The "common" source directory that is used for all ACPI components.

1a) Notes for Linux/Unix generation
-----------------------------------

iASL has been generated with these versions of Flex/Bison:

    flex:  Version 2.5.32
    bison: Version 2.6.2

Other required packages:

    make
    gcc C compiler
    m4 (macro processor required by bison)

On Linux/Unix systems, the following commands will build the compiler:

    cd acpica (or cd acpica/generate/unix)
    make clean
    make iasl

1b) Notes for Windows generation
--------------------------------

On Windows, the Visual Studio 2008 project file appears in this directory:

    generate/msvc9/AcpiComponents.sln

The Windows versions of GNU Flex/Bison must be installed, and they must
be installed in a directory that contains no embedded spaces in the
pathname. They cannot be installed in the default "c:\Program Files"
directory. This is a bug in Bison. The default Windows project file for
```

```
iASL assumes that these tools are installed at this location:

    c:\GnuWin32

Once the tools are installed, ensure that this path is added to the
default system $Path environment variable:

    c:\GnuWin32\bin

Goto: ControlPanel/System/AdvancedSystemSettings/EnvironmentVariables

Important: Now Windows must be rebooted to make the system aware of
the updated $Path. Otherwise, Bison will not be able to find the M4
interpreter library and will fail.

iASL has been generated with these versions of Flex/Bison for Windows:

    Flex for Windows:  V2.5.4a
    Bison for Windows: V2.4.1

Flex is available at:  http://gnuwin32.sourceforge.net/packages/flex.htm
Bison is available at: http://gnuwin32.sourceforge.net/packages/bison.htm

2) Integration as a custom tool for Visual Studio
-------------------------------------------------

This procedure adds the iASL compiler as a custom tool that can be used
to compile ASL source files. The output is sent to the VC output
window.

a) Select Tools->Customize.

b) Select the "Tools" tab.

c) Scroll down to the bottom of the "Menu Contents" window. There you
   will see an empty rectangle. Click in the rectangle to enter a
   name for this tool.

d) Type "iASL Compiler" in the box and hit enter. You can now edit
   the other fields for this new custom tool.

e) Enter the following into the fields:

   Command:             C:\Acpi\iasl.exe
   Arguments:           -vi "$(FilePath)"
   Initial Directory    "$(FileDir)"
   Use Output Window    <Check this option>

   "Command" must be the path to wherever you copied the compiler.
   "-vi" instructs the compiler to produce messages appropriate for VC.
   Quotes around FilePath and FileDir enable spaces in filenames.

f) Select "Close".

These steps will add the compiler to the tools menu as a custom tool.
By enabling "Use Output Window", you can click on error messages in
the output window and the source file and source line will be
automatically displayed by VC. Also, you can use F4 to step through
the messages and the corresponding source line(s).

3) Integrating iASL into a Visual Studio ASL project build
----------------------------------------------------------
```

```
128 This procedure creates a project that compiles ASL files to AML.

130 a) Create a new, empty project and add your .ASL files to the project

132 b) For all ASL files in the project, specify a custom build (under
133 Project/Settings/CustomBuild with the following settings (or similar):

135 Commands:
136     c:\acpi\libraries\iasl.exe -vs -vi "$(InputPath)"

138 Output:
139     $(InputDir)\$(InputPath).aml
```

/*
 * Note: History of _PRW support in ACPICA
 *
 * Originally (2000 - 2010), the GPE initialization code performed a walk of
 * the entire namespace to execute the _PRW methods and detect all GPEs
```

```
 * capable of waking the system.
 *
 * As of 10/2010, the _PRW method execution has been removed since it is
 * actually unnecessary. The host OS must in fact execute all _PRW methods
 * in order to identify the device/power-resource dependencies. We now put
 * the onus on the host OS to identify the wake GPEs as part of this process
 * and to inform ACPICA of these GPEs via the AcpiSetupGpeForWake interface. Thi
 * not only reduces the complexity of the ACPICA initialization code, but in
 * some cases (on systems with very large namespaces) it should reduce the
 * kernel boot time as well.

```

```
 * FUNCTION:    AcpiInstallNotifyHandler
 *
 * PARAMETERS:  Device          - The device for which notifies will be handled
 *              HandlerType     - The type of handler:
 *                                  ACPI_SYSTEM_NOTIFY: System Handler (00-7F)
 *                                  ACPI_DEVICE_NOTIFY: Device Handler (80-FF)
 *                                  ACPI_ALL_NOTIFY:    Both System and Device
 *              Handler         - Address of the handler
 *              Context         - Value passed to the handler on each GPE
 *
 * RETURN:      Status
 *
 * DESCRIPTION: Install a handler for notifications on an ACPI Device,
 *              ThermalZone, or Processor object.
 *
 * NOTES:       The Root namespace object may have only one handler for each
 *              type of notify (System/Device). Device/Thermal/Processor objects
 *              may have one device notify handler, and multiple system notify
 *              handlers.
 *

 *
 * FUNCTION:    AcpiExDoDebugObject
 *
```

```
 * PARAMETERS:  SourceDesc          - Object to be output to "Debug Object"
 *              Level               - Indentation level (used for packages)
 *              Index               - Current package element, zero if not pkg
 *
 * RETURN:      None
 *
 * DESCRIPTION: Handles stores to the AML Debug Object. For example:
 *              Store(INT1, Debug)
 *
 * This function is not compiled if ACPI_NO_ERROR_MESSAGES is set.
 *
 * This function is only enabled if AcpiGbl_EnableAmlDebugObject is set, or
 * if ACPI_LV_DEBUG_OBJECT is set in the AcpiDbgLevel. Thus, in the normal
 * operational case, stores to the debug object are ignored but can be easily
 * enabled if necessary.
 *

579  *
580  * FUNCTION:    AcpiExDoLogicalOp
581  *
582  * PARAMETERS:  Opcode              - AML opcode
583  *              Operand0            - operand #0
584  *              Operand1            - operand #1
585  *              LogicalResult       - TRUE/FALSE result of the operation
586  *
587  * RETURN:      Status
588  *
589  * DESCRIPTION: Execute a logical AML opcode. The purpose of having all of the
590  *              functions here is to prevent a lot of pointer dereferencing
591  *              to obtain the operands and to simplify the generation of the
592  *              logical value. For the Numeric operators (LAnd and LOr), both
593  *              operands must be integers. For the other logical operators,
594  *              operands can be any combination of Integer/String/Buffer. The
595  *              first operand determines the type to which the second operand
596  *              will be converted.
597  *
598  *              Note: cleanest machine code seems to be produced by the code
599  *              below, rather than using statements of the form:
```

```
 *                  Result = (Operand0 == Operand1);
 *

/*!
 * Naming convention for AML interpreter execution routines.
 *
 * The routines that begin execution of AML opcodes are named with a common
 * convention based upon the number of arguments, the number of target operands,
 * and whether or not a value is returned:
 *
 *      AcpiExOpcode_xA_yT_zR
 *
 * Where:
 *
 * xA - ARGUMENTS:    The number of arguments (input operands) that are
 *                    required for this opcode type (0 through 6 args).
 * yT - TARGETS:      The number of targets (output operands) that are required
 *                    for this opcode type (0, 1, or 2 targets).
 * zR - RETURN VALUE: Indicates whether this opcode type returns a value
 *                    as the function return (0 or 1).
 *
 * The AcpiExOpcode* functions are called via the Dispatcher component with
 * fully resolved operands.

/*!
```

```
 * Naming convention for AML interpreter execution routines.
 *
 * The routines that begin execution of AML opcodes are named with a common
 * convention based upon the number of arguments, the number of target operands,
 * and whether or not a value is returned:
 *
 *      AcpiExOpcode_xA_yT_zR
 *
 * Where:
 *
 * xA - ARGUMENTS:    The number of arguments (input operands) that are
 *                    required for this opcode type (1 through 6 args).
 * yT - TARGETS:      The number of targets (output operands) that are required
 *                    for this opcode type (0, 1, or 2 targets).
 * zR - RETURN VALUE: Indicates whether this opcode type returns a value
 *                    as the function return (0 or 1).
 *
 * The AcpiExOpcode* functions are called via the Dispatcher component with
 * fully resolved operands.

  58  * Naming convention for AML interpreter execution routines.
```

```
  59  *
  60  * The routines that begin execution of AML opcodes are named with a common
  61  * convention based upon the number of arguments, the number of target operands,
  62  * and whether or not a value is returned:
  63  *
  64  *      AcpiExOpcode_xA_yT_zR
  65  *
  66  * Where:
  67  *
  68  * xA - ARGUMENTS:    The number of arguments (input operands) that are
  69  *                    required for this opcode type (1 through 6 args).
  70  * yT - TARGETS:      The number of targets (output operands) that are required
  71  *                    for this opcode type (0, 1, or 2 targets).
  72  * zR - RETURN VALUE: Indicates whether this opcode type returns a value
  73  *                    as the function return (0 or 1).
  74  *
  75  * The AcpiExOpcode* functions are called via the Dispatcher component with
  76  * fully resolved operands.
