1031 /*
1032  * Unsolved problem: if a type is actually a pointer type, like
1033  * nid_triple is, then its impossible to get a const where you need
1034  * it. Consider:
1035  *
1036  * typedef int nid_triple[3];
1037  * const void *a;
1038  * const nid_triple const *a = a;
1039  *
1040  * The assignment discards a const because what you really want is:
1041  *
1042  * const int const * const *a = a;
1043  *
1044  * But if you do that, you lose the fact that a is an array of 3 ints,
1045  * which breaks comparison functions.
1046  *
1047  * Thus we end up having to cast, sadly, or unpack the
1048  * declarations. Or, as I finally did in this case, declare nid_triple
1049  * to be a struct, which it should have been in the first place.
1050  *
1051  * Ben, August 2008.

```

```

1052 *
1053 * Also, strictly speaking not all types need be const, but handling
1054 * the non-constness means a lot of complication, and in practice

288  The value for "signature" is specified in the OCSP rfc2560 as follows:
289  "The value for the signature SHALL be computed on the hash of the DER
290  encoding ResponseData." This means that you must hash the DER-encoded
291  tbsResponseData, and then run it through a crypto-signing function, which
292  will (at least w/RSA) do a hash-'n'-private-encrypt operation. This seems
293  a bit odd, but that's the spec. Also note that the data structures do not
294  leave anywhere to independently specify the algorithm used for the initial
295  hash. So, we look at the signature-specification algorithm, and try to do
296  something intelligent. -- Kathy Weinhold, CertCo */
297 /* Note 2:
298  It seems that the mentioned passage from RFC 2560 (section 4.2.1) is open
299  for interpretation. I've done tests against another responder, and found
300  that it doesn't do the double hashing that the RFC seems to say one
301  should. Therefore, all relevant functions take a flag saying which
302  variant should be used. -- Richard Levitte, OpenSSL team and CeloCom */

1 #ifndef HEADER_OPENSSLV_H
2 #define HEADER_OPENSSLV_H

4 /* Numeric release version identifier:
5 * MNNFFPPS: major minor fix patch status
6 * The status nibble has one of the values 0 for development, 1 to e for betas
7 * 1 to 14, and f for release. The patch level is exactly that.
8 * For example:
9 * 0.9.3-dev      0x00903000
10 * 0.9.3-beta1   0x00903001
11 * 0.9.3-beta2-dev 0x00903002
12 * 0.9.3-beta2   0x00903002 (same as ...beta2-dev)
13 * 0.9.3         0x0090300f
14 * 0.9.3a        0x0090301f
15 * 0.9.4         0x0090400f
16 * 1.2.3z        0x102031af
17 *
18 * For continuity reasons (because 0.9.5 is already out, and is coded
19 * 0x00905100), between 0.9.5 and 0.9.6 the coding of the patch level
20 * part is slightly different, by setting the highest bit. This means
21 * that 0.9.5a looks like this: 0x0090581f. At 0.9.6, we can start
22 * with 0x0090600S...
23 *
24 * (Prior to 0.9.3-dev a different scheme was used: 0.9.2b is 0x0922.)
25 * (Prior to 0.9.5a beta1, a different scheme was used: MMNFFRBB for
26 * major minor fix final patch/beta)
27 */

34 #define OPENSSL_VERSION_PTEXT " part of " OPENSSL_VERSION_TEXT

37 /* The macros below are to be used for shared library (.so, .dll, ...)
38 * versioning. That kind of versioning works a bit differently between
39 * operating systems. The most usual scheme is to set a major and a minor
40 * number, and have the runtime loader check that the major number is equal
41 * to what it was at application link time, while the minor number has to
42 * be greater or equal to what it was at application link time. With this
43 * scheme, the version number is usually part of the file name, like this:
44 *
45 *     libcrypto.so.0.9
46 *
47 * Some unixen also make a softlink with the major version number only:
48 *
49 *     libcrypto.so.0
50 *
51 * On Tru64 and IRIX 6.x it works a little bit differently. There, the
52 * shared library version is stored in the file, and is actually a series
53 * of versions, separated by colons. The rightmost version present in the
54 * library when linking an application is stored in the application to be
55 * matched at run time. When the application is run, a check is done to
56 * see if the library version stored in the application matches any of the
57 * versions in the version string of the library itself.
58 * This version string can be constructed in any way, depending on what
59 * kind of matching is desired. However, to implement the same scheme as
60 * the one used in the other unixen, all compatible versions, from lowest
61 * to highest, should be part of the string. Consecutive builds would
```

new/usr/src/lib/openssl/include/openssl/openssl.h

2

```
62 * give the following versions strings:
63 *
64 *     3.0
65 *     3.0:3.1
66 *     3.0:3.1:3.2
67 *     4.0
68 *     4.0:4.1
69 *
70 * Notice how version 4 is completely incompatible with version, and
71 * therefore give the breach you can see.
72 *
73 * There may be other schemes as well that I haven't yet discovered.
74 *
75 * So, here's the way it works here: first of all, the library version
76 * number doesn't need at all to match the overall OpenSSL version.
77 * However, it's nice and more understandable if it actually does.
78 * The current library version is stored in the macro SHLIB_VERSION_NUMBER,
79 * which is just a piece of text in the format "M.m.e" (Major, minor, edit).
80 * For the sake of Tru64, IRIX, and any other OS that behaves in similar ways,
81 * we need to keep a history of version numbers, which is done in the
82 * macro SHLIB_VERSION_HISTORY. The numbers are separated by colons and
83 * should only keep the versions that are binary compatible with the current.
84 */
85 #define SHLIB_VERSION_HISTORY ""
86 #define SHLIB_VERSION_NUMBER "1.0.0"

87 /* The following functions are used to add strings to be printed and prompt
88 strings to prompt for data. The names are UI_{add,dup}_{function}_string
89 and UI_{add,dup}_input_boolean.

91 UI_{add,dup}_{function}_string have the following meanings:
92 add add a text or prompt string. The pointers given to these
93 functions are used verbatim, no copying is done.
94 dup make a copy of the text or prompt string, then add the copy
95 to the collection of strings in the user interface.
96 <function>
97 The function is a name for the functionality that the given
98 string shall be used for. It can be one of:
99 input use the string as data prompt.
100 verify use the string as verification prompt. This
101 is used to verify a previous input.
102 info use the string for informational output.
103 error use the string for error output.
104 Honestly, there's currently no difference between info and error for the
105 moment.

107 UI_{add,dup}_input_boolean have the same semantics for "add" and "dup",
108 and are typically used when one wants to prompt for a yes/no response.

111 All of the functions in this group take a UI and a prompt string.
112 The string input and verify addition functions also take a flag argument,
113 a buffer for the result to end up with, a minimum input size and a maximum
114 input size (the result buffer MUST be large enough to be able to contain
115 the maximum number of characters). Additionally, the verify addition
116 functions takes another buffer to compare the result against.
117 The boolean input functions take an action description string (which should
118 be safe to ignore if the expected user action is obvious, for example with
119 a dialog box with an OK button and a Cancel button), a string of acceptable
120 characters to mean OK and to mean Cancel. The two last strings are checked
121 to make sure they don't have common characters. Additionally, the same
122 flag argument as for the string input is taken, as well as a result buffer.
123 The result buffer is required to be at least one byte long. Depending on
124 the answer, the first character from the OK or the Cancel character strings
125 will be stored in the first byte of the result buffer. No NUL will be
126 added, so the result is *not* a string.

```

```

128 On success, the all return an index of the added information. That index
129 is usefull when retrieving results with UI_get0_result(). */

151 #define UI_INPUT_FLAG_ECHO 0x01
152 /* Use a default password. Where that password is found is completely
153 up to the application, it might for example be in the user data set
154 with UI_add_user_data(). It is not recommended to have more than
155 one input in each UI being marked with this flag, or the application
156 might get confused. */
157 #define UI_INPUT_FLAG_DEFAULT_PWD 0x02

159 /* The user of these routines may want to define flags of their own. The core
160 UI won't look at those, but will pass them on to the method routines. They
161 must use higher bits so they don't get confused with the UI bits above.
162 UI_INPUT_FLAG_USER_BASE tells which is the lowest bit to use. A good
163 example of use is this:

165     #define MY_UI_FLAG1 (0x01 << UI_INPUT_FLAG_USER_BASE)

167 */
168 #define UI_INPUT_FLAG_USER_BASE 16

171 /* The following function helps construct a prompt. object_desc is a
172 textual short description of the object, for example "pass phrase",
173 and object_name is the name of the object (might be a card name or
174 a file name.
175 The returned string shall always be allocated on the heap with
176 OPENSSL_malloc(), and need to be free'd with OPENSSL_free().

178 If the ui_method doesn't contain a pointer to a user-defined prompt
179 constructor, a default string is built, looking like this:

181     "Enter {object_desc} for {object_name}:"

183 So, if object_desc has the value "pass phrase" and object_name has
184 the value "foo.key", the resulting string is:

186     "Enter pass phrase for foo.key:"
187 */
188 char *UI_construct_prompt(UI *ui_method,
189     const char *object_desc, const char *object_name);

192 /* The following function is used to store a pointer to user-specific data.
193 Any previous such pointer will be returned and replaced.
```

```

195 For callback purposes, this function makes a lot more sense than using
196 ex_data, since the latter requires that different parts of OpenSSL or
197 applications share the same ex_data index.

199 Note that the UI_OpenSSL() method completely ignores the user data.
200 Other methods may not, however. */

241 /* The method with all the built-in thingies */
242 UI_METHOD *UI_OpenSSL(void);

245 /* ----- For method writers ----- */
246 /* A method contains a number of functions that implement the low level
247 of the User Interface. The functions are:

249 an opener This function starts a session, maybe by opening
250 a channel to a tty, or by opening a window.
251 a writer This function is called to write a given string,
252 maybe to the tty, maybe as a field label in a
253 window.
254 a flusher This function is called to flush everything that
255 has been output so far. It can be used to actually
256 display a dialog box after it has been built.
257 a reader This function is called to read a given prompt,
258 maybe from the tty, maybe from a field in a
259 window. Note that it's called with all string
```

```

260     structures, not only the prompt ones, so it must
261     check such things itself.
262     a closer    This function closes the session, maybe by closing
263                 the channel to the tty, or closing the window.

265     All these functions are expected to return:

267         0        on error.
268         1        on success.
269        -1        on out-of-band events, for example if some prompting has
270                  been canceled (by pressing Ctrl-C, for example). This is
271                  only checked when returned by the flusher or the reader.

273     The way this is used, the opener is first called, then the writer for all
274     strings, then the flusher, then the reader for all strings and finally the
275     closer. Note that if you want to prompt from a terminal or other command
276     line interface, the best is to have the reader also write the prompts
277     instead of having the writer do it. If you want to prompt from a dialog
278     box, the writer can be used to build up the contents of the box, and the
279     flusher to actually display the box and run the event loop until all data
280     has been given, after which the reader only grabs the given data and puts
281     them back into the UI strings.

283     All method functions take a UI as argument. Additionally, the writer and
284     the reader take a UI_STRING.

24 #endif

26 /* Before including this file (pkcs11.h) (or pkcs11t.h by
27  * itself), 6 platform-specific macros must be defined. These
28  * macros are described below, and typical definitions for them
29  * are also given. Be advised that these definitions can depend
30  * on both the platform and the compiler used (and possibly also
31  * on whether a Cryptoki library is linked statically or
32  * dynamically).
33  *
34  * In addition to defining these 6 macros, the packing convention
35  * for Cryptoki structures should be set. The Cryptoki
36  * convention on packing is that structures should be 1-byte
37  * aligned.
38  *
39  * If you're using Microsoft Developer Studio 5.0 to produce
40  * Win32 stuff, this might be done by using the following
41  * preprocessor directive before including pkcs11.h or pkcs11t.h:
42  *
43  * #pragma pack(push, cryptoki, 1)
44  *
45  * and using the following preprocessor directive after including
46  * pkcs11.h or pkcs11t.h:
47  *
48  * #pragma pack(pop, cryptoki)
49  *
50  * If you're using an earlier version of Microsoft Developer
51  * Studio to produce Win16 stuff, this might be done by using
52  * the following preprocessor directive before including
53  * pkcs11.h or pkcs11t.h:
54  *
55  * #pragma pack(1)
56  *
57  * In a UNIX environment, you're on your own for this. You might
58  * not need to do (or be able to do!) anything.
59  *
60  *
61  * Now for the macros:
```

new/usr/src/lib/openssl/include/pkcs11.h

2

```
62 *
63 *
64 * 1. CK_PTR: The indirection string for making a pointer to an
65 * object. It can be used like this:
66 *
67 * typedef CK_BYTE CK_PTR CK_BYTE_PTR;
68 *
69 * If you're using Microsoft Developer Studio 5.0 to produce
70 * Win32 stuff, it might be defined by:
71 *
72 * #define CK_PTR *
73 *
74 * If you're using an earlier version of Microsoft Developer
75 * Studio to produce Win16 stuff, it might be defined by:
76 *
77 * #define CK_PTR far *
78 *
79 * In a typical UNIX environment, it might be defined by:
80 *
81 * #define CK_PTR *
82 *
83 *
84 * 2. CK_DECLARE_FUNCTION(returnType, name): A macro which makes
85 * an exportable Cryptoki library function definition out of a
86 * return type and a function name. It should be used in the
87 * following fashion to define the exposed Cryptoki functions in
88 * a Cryptoki library:
89 *
90 * CK_DECLARE_FUNCTION(CK_RV, C_Initialize)(
91 *     CK_VOID_PTR pReserved
92 * )
93 * {
94 *     ...
95 * }
96 *
97 * If you're using Microsoft Developer Studio 5.0 to define a
98 * function in a Win32 Cryptoki .dll, it might be defined by:
99 *
100 * #define CK_DECLARE_FUNCTION(returnType, name) \
101 *     returnType __declspec(dllexport) name
102 *
103 * If you're using an earlier version of Microsoft Developer
104 * Studio to define a function in a Win16 Cryptoki .dll, it
105 * might be defined by:
106 *
107 * #define CK_DECLARE_FUNCTION(returnType, name) \
108 *     returnType __export _far _pascal name
109 *
110 * In a UNIX environment, it might be defined by:
111 *
112 * #define CK_DECLARE_FUNCTION(returnType, name) \
113 *     returnType name
114 *
115 *
116 * 3. CK_DECLARE_FUNCTION(returnType, name): A macro which makes
117 * an importable Cryptoki library function declaration out of a
118 * return type and a function name. It should be used in the
119 * following fashion:
120 *
121 * extern CK_DECLARE_FUNCTION(CK_RV, C_Initialize)(
122 *     CK_VOID_PTR pReserved
123 * );
124 *
125 * If you're using Microsoft Developer Studio 5.0 to declare a
126 * function in a Win32 Cryptoki .dll, it might be defined by:
127 *
```

```

128 * #define CK_DECLARE_FUNCTION(returnType, name) \
129 *     returnType __declspec(dllimport) name
130 *
131 * If you're using an earlier version of Microsoft Developer
132 * Studio to declare a function in a Win16 Cryptoki .dll, it
133 * might be defined by:
134 *
135 * #define CK_DECLARE_FUNCTION(returnType, name) \
136 *     returnType __export _far _pascal name
137 *
138 * In a UNIX environment, it might be defined by:
139 *
140 * #define CK_DECLARE_FUNCTION(returnType, name) \
141 *     returnType name
142 *
143 *
144 * 4. CK_DECLARE_FUNCTION_POINTER(returnType, name): A macro
145 * which makes a Cryptoki API function pointer declaration or
146 * function pointer type declaration out of a return type and a
147 * function name. It should be used in the following fashion:
148 *
149 * // Define funcPtr to be a pointer to a Cryptoki API function
150 * // taking arguments args and returning CK_RV.
151 * CK_DECLARE_FUNCTION_POINTER(CK_RV, funcPtr)(args);
152 *
153 * or
154 *
155 * // Define funcPtrType to be the type of a pointer to a
156 * // Cryptoki API function taking arguments args and returning
157 * // CK_RV, and then define funcPtr to be a variable of type
158 * // funcPtrType.
159 * typedef CK_DECLARE_FUNCTION_POINTER(CK_RV, funcPtrType)(args);
160 * funcPtrType funcPtr;
161 *
162 * If you're using Microsoft Developer Studio 5.0 to access
163 * functions in a Win32 Cryptoki .dll, it might be defined by:
164 *
165 * #define CK_DECLARE_FUNCTION_POINTER(returnType, name) \
166 *     returnType __declspec(dllimport) (* name)
167 *
168 * If you're using an earlier version of Microsoft Developer
169 * Studio to access functions in a Win16 Cryptoki .dll, it might
170 * be defined by:
171 *
172 * #define CK_DECLARE_FUNCTION_POINTER(returnType, name) \
173 *     returnType __export _far _pascal (* name)
174 *
175 * In a UNIX environment, it might be defined by:
176 *
177 * #define CK_DECLARE_FUNCTION_POINTER(returnType, name) \
178 *     returnType (* name)
179 *
180 *
181 * 5. CK_CALLBACK_FUNCTION(returnType, name): A macro which makes
182 * a function pointer type for an application callback out of
183 * a return type for the callback and a name for the callback.
184 * It should be used in the following fashion:
185 *
186 * CK_CALLBACK_FUNCTION(CK_RV, myCallback)(args);
187 *
188 * to declare a function pointer, myCallback, to a callback
189 * which takes arguments args and returns a CK_RV. It can also
190 * be used like this:
191 *
192 * typedef CK_CALLBACK_FUNCTION(CK_RV, myCallbackType)(args);
193 * myCallbackType myCallback;

```

```

194 *
195 * If you're using Microsoft Developer Studio 5.0 to do Win32
196 * Cryptoki development, it might be defined by:
197 *
198 * #define CK_CALLBACK_FUNCTION(returnType, name) \
199 *     returnType (* name)
200 *
201 * If you're using an earlier version of Microsoft Developer
202 * Studio to do Win16 development, it might be defined by:
203 *
204 * #define CK_CALLBACK_FUNCTION(returnType, name) \
205 *     returnType _far _pascal (* name)
206 *
207 * In a UNIX environment, it might be defined by:
208 *
209 * #define CK_CALLBACK_FUNCTION(returnType, name) \
210 *     returnType (* name)
211 *
212 *
213 * 6. NULL_PTR: This macro is the value of a NULL pointer.
214 *
215 * In any ANSI/ISO C environment (and in many others as well),
216 * this should best be defined by
217 *
218 * #ifndef NULL_PTR
219 * #define NULL_PTR 0
220 * #endif

89 /*
90 * This converts an ASN1 INTEGER into its content encoding.
91 * The internal representation is an ASN1_STRING whose data is a big endian
92 * representation of the value, ignoring the sign. The sign is determined by
93 * the type: V_ASN1_INTEGER for positive and V_ASN1_NEG_INTEGER for negative.
94 *
95 * Positive integers are no problem: they are almost the same as the DER
96 * encoding, except if the first byte is >= 0x80 we need to add a zero pad.
97 *
98 * Negative integers are a bit trickier...
99 * The DER representation of negative integers is in 2s complement form.
100 * The internal form is converted by complementing each octet and finally
101 * adding one to the result. This can be done less messily with a little trick.
102 * If the internal form has trailing zeroes then they will become FF by the
103 * complement and 0 by the add one (due to carry) so just copy as many trailing
104 * zeros to the destination as there are in the source. The carry will add one
105 * to the last none zero octet: so complement this octet and add one and finally
106 * complement any left over until you get to the start of the string.
107 *
108 * Padding is a little trickier too. If the first bytes is > 0x80 then we pad
109 * with 0xff. However if the first byte is 0x80 and one of the following bytes
110 * is non-zero we pad with 0xff. The reason for this distinction is that 0x80
111 * followed by optional zeros isn't padded.

62 /* Experimental NDEF ASN1 BIO support routines */
63
64 /* The usage is quite simple, initialize an ASN1 structure,
65  * get a BIO from it then any data written through the BIO
66  * will end up translated to appropriate format on the fly.
67  * The data is streamed out and does *not* need to be
68  * all held in memory at once.
69  *
70  * When the BIO is flushed the output is finalized and any
71  * signatures etc written out.
72  *
73  * The BIO is a 'proper' BIO and can handle non blocking I/O
74  * correctly.
75  *
76  * The usage is simple. The implementation is *not*...
