103 /* This function determines how parameters are "inherited" from one structure
104  * to another. There are several different ways this can happen.
105  *
106  * 1. If a child structure needs to have its values initialized from a parent
107  * they are simply copied across. For example SSL_CTX copied to SSL.
108  * 2. If the structure should take on values only if they are currently unset.
109  * For example the values in an SSL structure will take appropriate value
110  * for SSL servers or clients but only if the application has not set new
111  * ones.
112  *
113  * The "inh_flags" field determines how this function behaves.
114  *
115  * Normally any values which are set in the default are not copied from the
116  * destination and verify flags are Ored together.
117  *
118  * If X509_VP_FLAG_DEFAULT is set then anything set in the source is copied
119  * to the destination. Effectively the values in "to" become default values
120  * which will be used only if nothing new is set in "from".
121  *
122  * If X509_VP_FLAG_OVERWRITE is set then all value are copied across whether
123  * they are set or not. Flags is still Ored though.
124  *
125  * If X509_VP_FLAG_RESET_FLAGS is set then the flags value is copied instead
126  * of Ored.
127  */
```

```

128 * If X509_VP_FLAG_LOCKED is set then no values are copied.
129 *
130 * If X509_VP_FLAG_ONCE is set then the current inh_flags setting is zeroed
131 * after the next call.
132 */

```

```

722 * 'type' is one of the following:
723 *
724 * - SSL3_RT_HANDSHAKE (when ssl3_get_message calls us)
725 * - SSL3_RT_APPLICATION_DATA (when ssl3_read calls us)
726 * - 0 (during a shutdown, no data has to be returned)
727 *
728 * If we don't have stored data to work from, read a SSL/TLS record first
729 * (possibly multiple records if we still don't have anything to return).
730 *
731 * This function must handle any surprises the peer may have for us, such as
732 * Alert records (e.g. close_notify), ChangeCipherSpec records (not really
733 * a surprise, but handled as if it were), or renegotiation requests.
734 * Also if record payloads contain fragments too small to process, we store
735 * them until there is enough for the respective protocol (the record protocol
736 * may use arbitrary fragmentation and even interleaving):
737 *   Change cipher spec protocol
738 *       just 1 byte needed, no need for keeping anything stored
739 *   Alert protocol
740 *       2 bytes needed (AlertLevel, AlertDescription)
741 *   Handshake protocol
742 *       4 bytes needed (HandshakeType, uint24 length) -- we just have
743 *       to detect unexpected Client Hello and Hello Request messages
744 *       here, anything else is handled by higher layers
745 *   Application data protocol
746 *       none of our business

668 #ifndef OPENSLL_NO_BUF_FREELISTS
669 /* On some platforms, malloc() performance is bad enough that you can't just
670 * free() and malloc() buffers all the time, so we need to use freelists from
671 * unused buffers. Currently, each freelist holds memory chunks of only a
672 * given size (list->chunklen); other sized chunks are freed and malloced.
673 * This doesn't help much if you're using many different SSL option settings
674 * with a given context. (The options affecting buffer size are
675 * max_send_fragment, read buffer vs write buffer,
676 * SSL_OP_MICROSOFT_BIG_WRITE_BUFFER, SSL_OP_NO_COMPRESSION, and
677 * SSL_OP_DONT_INSERT_EMPTY_FRAGMENTS.) Using a separate freelist for every
678 * possible size is not an option, since max_send_fragment can take on many
679 * different values.
680 *
681 * If you are on a platform with a slow malloc(), and you're using SSL
682 * connections with many different settings for these options, and you need to
683 * use the SSL_MOD_RELEASE_BUFFERS feature, you have a few options:
684 * - Link against a faster malloc implementation.
685 * - Use a separate SSL_CTX for each option set.
686 * - Improve this code.

691          * an SSLv2/v3 compatible client hello). The client_version
692          * field is the maximum version we permit and it is also
693          * used in RSA encrypted premaster secrets. Some servers can
694          * choke if we initially report a higher version then
695          * renegotiate to a lower one in the premaster secret. This
696          * didn't happen with TLS 1.0 as most servers supported it
697          * but it can with TLS 1.1 or later if the server only supports
698          * 1.0.
699          *
700          * Possible scenario with previous logic:
701          * 1. Client hello indicates TLS 1.2
702          * 2. Server hello says TLS 1.0
703          * 3. RSA encrypted premaster secret uses 1.2.
704          * 4. Handhaked proceeds using TLS 1.0.
705          * 5. Server sends hello request to renegotiate.
706          * 6. Client hello indicates TLS v1.0 as we now
707          *    know that is maximum server supports.
708          * 7. Server chokes on RSA encrypted premaster secret
709          *    containing version 1.0.
710          *
711          * For interoperability it should be OK to always use the
712          * maximum version we support in client hello and then rely
713          * on the checking of version to ensure the servers isn't
714          * being inconsistent: for example initially negotiating with
715          * TLS 1.0 and renegotiating with TLS 1.2. We do this by using
716          * client_version in client hello and not resetting it to
717          * the negotiated version.

1517 /* SSL_select_next_proto implements the standard protocol selection. It is
1518  * expected that this function is called from the callback set by
1519  * SSL_CTX_set_next_proto_select_cb.
1520  *
1521  * The protocol data is assumed to be a vector of 8-bit, length prefixed byte
1522  * strings. The length byte itself is not included in the length. A byte
1523  * string of length 0 is invalid. No byte string may be truncated.
1524  *
1525  * The current, but experimental algorithm for selecting the protocol is:
1526  *
1527  * 1) If the server doesn't support NPN then this is indicated to the
1528  * callback. In this case, the client application has to abort the connection
1529  * or have a default application level protocol.
1530  *
1531  * 2) If the server supports NPN, but advertises an empty list then the
1532  * client selects the first protocol in its list, but indicates via the
1533  * API that this fallback case was enacted.
1534  *
1535  * 3) Otherwise, the client finds the first protocol in the server's list
1536  * that it supports and selects this protocol. This is because it's
1537  * assumed that the server has better information about which protocol
1538  * a client should use.
1539  *
1540  * 4) If the client doesn't support any of the server's advertised
1541  * protocols, then this is treated the same as case 2.
1542  *
1543  * It returns either
1544  * OPENSSE_NPN_NEGOTIATED if a common protocol was found, or
1545  * OPENSSE_NPN_NO_OVERLAP if the fallback case was reached.

1020
1021          - Only the hostname type is supported with a maximum length of 255.
1022          - The servername is rejected if too long or if it contains zeros,
1023            in which case a fatal alert is generated.
1024          - The servername field is maintained together with the session cache.
1025          - When a session is resumed, the servername call back invoked in order
1026            to allow the application to position itself to the right context.
1027          - The servername is acknowledged if it is new for a session or when
1028            it is identical to a previously used for the same session.
1029            Applications can control the behaviour. They can at any time
1030            set a 'desirable' servername for a new SSL object. This can be the
1031            case for example with HTTPS when a Host: header field is received and
1032            a renegotiation is requested. In this case, a possible servername
1033            presented in the new client hello is only acknowledged if it matches
1034            the value of the Host: field.
1035          - Applications must use SSL_OP_NO_SESSION_RESUMPTION_ON_RENEGOTIATION
1036            if they provide for changing an explicit servername context for the session
1037            i.e. when the session has been established with a servername extension.
1038          - On session reconnect, the servername extension may be absent.
