544          * Why oh why did they bother with negotiating langs for
545          * each protocol direction?!
546          *
547          * The semantics of this are vaguely specified, but one can
548          * imagine using one language (locale) for the whole session and
549          * a different one for message localization (e.g., 'en_US.UTF-8'
550          * overall and 'fr' for messages). Weird? Maybe. But lang
551          * tags don't include codeset info, like locales do...
552          *
553          * So, server-side we want:
554          * - setlocale(LC_ALL, c2s_locale);
555          * and
556          * - setlocale(LC_MESSAGES, s2c_locale);
557          *
558          * Client-side we don't really care. But we could do:
559          *
560          * - when very verbose, tell the use what lang the server's
561          *   messages are in, if left out in the protocol
562          * - when sending messages to the server, and if applicable, we
563          *   can localize them according to the language negotiated for
564          *   that direction.
565          *
566          * But for now we do nothing on the client side.

401 /*
402  * Yes, we harcode OIDs for some things, for now it's all we can do.
403  *
404  * We have to reference particular mechanisms due to lack of generality
405  * in the GSS-API in several areas: authorization, mapping principal
406  * names to usernames, "storing" delegated credentials, and discovering
407  * whether a mechanism is a pseudo-mechanism that negotiates mechanisms.
408  *
409  * Even if they were in some header file or if __gss_mech_to_oid()
410  * and/or __gss_oid_to_mech() were standard we'd still have to hardcode
411  * the mechanism names, and since the mechanisms have no standard names
412  * other than their OIDs it's actually worse [less portable] to hardcode
413  * names than OIDs, so we hardcode OIDs.
414  *
415  * SPNEGO is a difficult problem though -- it MUST NOT be used in SSHv2,
416  * but that's true of all possible pseudo-mechanisms that can perform
417  * mechanism negotiation, and SPNEGO could have new OIDs in the future.
418  * Ideally we could query each mechanism for its feature set and then
419  * ignore any mechanisms that negotiate mechanisms, but, alas, there's
420  * no interface to do that.
421  *
422  * In the future, if the necessary generic GSS interfaces for the issues
423  * listed above are made available (even if they differ by platform, as
424  * we can expect authorization interfaces will), then we can stop
425  * referencing specific mechanism OIDs here.

884 * http_process_headers - Read in the header lines from the response
885 *
886 *     ret = http_process_headers(handle, resp);
887 *
888 * Arguments:
889 *     handle - Handle associated with the connection where the request
890 *               was made.
891 *     resp - Summary information about the response.
892 *
893 * Returns:
894 *     0 - Success
895 *    < 0 - An error occurred. Specifics of the error can
896 *          be gotten using http_get_lasterr().
897 *
898 * Process the HTTP headers in the response. Check for a valid response
899 * status line. Allocate and return response information via the 'resp'
900 * argument. Header lines are stored locally, are returned using calls
901 * to http_get_response_header() and http_get_header_value().
902 *
903 * Note that the errors will be set in the http_conn_t struct before the
904 * function which detected the error returns.
905 *
906 * Note that if resp is non-NULL, then upon a successful return, information
907 * about the status line, the code in the status line and the number of
908 * header lines are returned in the http_respinfo_t structure. The caller is
909 * responsible for freeing the resources allocated to this structure via
910 * http_free_respinfo().
911 *
912 * Note that the counters used to read message bodies are initialized here.
913 *
914 * Calling this function replaces the header information which is
915 * queried using http_get_response_header() and http_get_header_value().
916 * Once this function is called, headers read by the previous call
917 * to http_process_headers() or http_process_part_headers() is lost.
918 */

30 # Note that libcurses installs commands along with its library.
31 # This is a minor bug which probably should be fixed.
32 # Note also that a few extra libraries are kept in cmd source.
33 #
34 # Certain libraries are linked with, hence depend on, other libraries.
35 #
36 # Although we have historically used .WAIT to express dependencies, it
37 # reduces the amount of parallelism and thus lengthens the time it
38 # takes to build the libraries. Thus, we now require that any new
39 # libraries explicitly call out their dependencies. Eventually, all
40 # the library dependencies will be called out explicitly. See
41 # "Library interdependencies" near the end of this file.
42 #
43 # Aside from explicit dependencies (and legacy .WAITs), all libraries
44 # are built in parallel.
45 #
46 .PARALLEL:

530 .KEEP_STATE:

532 #
533 # For the all and install targets, we clearly must respect library
534 # dependencies so that the libraries link correctly. However, for
535 # the remaining targets (check, clean, clobber, install_h, lint, _dc
536 # and _msg), libraries do not have any dependencies on one another
537 # and thus respecting dependencies just slows down the build.
538 # As such, for these rules, we use pattern replacement to explicitly
539 # avoid triggering the dependency information. Note that for clean,
540 # clobber and lint, we must use $(NOWAIT_SUBDIRS) rather than
541 # $(SUBDIRS), to prevent '.WAIT' from expanding to '.WAIT-nodepend'.
542 #

544 all:              $(SUBDIRS)

123  * BN_window_bits_for_exponent_size -- macro for sliding window mod_exp function
124  *
125  * For window size 'w' (w >= 2) and a random 'b' bits exponent,
126  * the number of multiplications is a constant plus on average
```

```

128 *
129 *      2^(w-1) + (b-w)/(w+1);
130 *
131 * here 2^(w-1) is for precomputing the table (we actually need
132 * entries only for windows that have the lowest bit set), and
133 * (b-w)/(w+1) is an approximation for the expected number of
134 * w-bit windows, not counting the first one.
135 *
136 * Thus we should use
137 *
138 *      w >= 6 if      b > 671
139 *      w = 5 if 671 > b > 239
140 *      w = 4 if 239 > b > 79
141 *      w = 3 if 79 > b > 23
142 *      w <= 2 if 23 > b
143 *
144 * (with draws in between). Very small exponents are often selected
145 * with low Hamming weight, so we use w = 1 for b <= 23.

215 * BN_UMULT_HIGH section.
216 *
217 * No, I'm not trying to overwhelm you when stating that the
218 * product of N-bit numbers is 2*N bits wide:-) No, I don't expect
219 * you to be impressed when I say that if the compiler doesn't
220 * support 2*N integer type, then you have to replace every N*N
221 * multiplication with 4 (N/2)*(N/2) accompanied by some shifts
222 * and additions which unavoidably results in severe performance
223 * penalties. Of course provided that the hardware is capable of
224 * producing 2*N result... That's when you normally start
225 * considering assembler implementation. However! It should be
226 * pointed out that some CPUs (most notably Alpha, PowerPC and
227 * upcoming IA-64 family:-) provide *separate* instruction
228 * calculating the upper half of the product placing the result
229 * into a general purpose register. Now *if* the compiler supports
230 * inline assembler, then it's not impossible to implement the
231 * "bignum" routines (and have the compiler optimize 'em)
232 * exhibiting "native" performance in C. That's what BN_UMULT_HIGH
233 * macro is about:-)
234 *

361 #endif

363 /* IP and FP
364  * The problem is more of a geometric problem than random bit fiddling.
365  *
366  * 0 1 2 3 4 5 6 7      62 54 46 38 30 22 14 6
367  * 8 9 10 11 12 13 14 15    60 52 44 36 28 20 12 4
368  * 16 17 18 19 20 21 22 23    58 50 42 34 26 18 10 2
369  * 24 25 26 27 28 29 30 31    to 56 48 40 32 24 16 8 0

370  * 32 33 34 35 36 37 38 39    63 55 47 39 31 23 15 7
371  * 40 41 42 43 44 45 46 47    61 53 45 37 29 21 13 5
372  * 48 49 50 51 52 53 54 55    59 51 43 35 27 19 11 3
373  * 56 57 58 59 60 61 62 63    57 49 41 33 25 17 9 1

375  The output has been subject to swaps of the form
376  0 1 -> 3 1 but the odd and even bits have been put into
377  2 3 2 0
378  different words. The main trick is to remember that
379  t=((l>>size)^r)&(mask);
380  r^=t;
381  l^=(t<<size);
382  can be used to swap and move bits between words.

384  So l = 0 1 2 3 r = 16 17 18 19
385  4 5 6 7      20 21 22 23
386  8 9 10 11     24 25 26 27
387  12 13 14 15   28 29 30 31
388  becomes (for size == 2 and mask == 0x3333)
389  t = 2^16 3^17 -- -- l = 0 1 16 17 r = 2 3 18 19
390  6^20 7^21 -- --      4 5 20 21      6 7 22 23
391  10^24 11^25 -- --    8 9 24 25      10 11 24 25

```

```

392          14^28 15^29 -- --      12 13 28 29      14 15 28 29

394      Thanks for hints from Richard Outerbridge - he told me IP&FP
395      could be done in 15 xor, 10 shifts and 5 ands.
396      When I finally started to think of the problem in 2D
397      I first got ~42 operations without xors. When I remembered
398      how to use xors :-) I got it to its final state.

395 /* We don't have any well-defined random devices on VMS, yet... */
396 # undef DEVRANDOM
397 /* We need to do this since VMS has the following coding on status codes:
398
399 Bits 0-2: status type: 0 = warning, 1 = success, 2 = error, 3 = info ...
400 The important thing to know is that odd numbers are considered
401 good, while even ones are considered errors.
402 Bits 3-15: actual status number
403 Bits 16-27: facility number. 0 is considered "unknown"
404 Bits 28-31: control bits. If bit 28 is set, the shell won't try to
405 output the message (which, for random codes, just looks ugly)
406
407 So, what we do here is to change 0 to 1 to get the default success status,
408 and everything else is shifted up to fit into the status number field, and
409 the status is tagged as an error, which I believe is what is wanted here.

292 /*
293  * We have 3 different groups of operation types:
294  * 1) asymmetric operations
295  * 2) random operations
296  * 3) symmetric and digest operations
297  *
298  * This division into groups stems from the fact that it's common that hardware
299  * providers may support operations from one group only. For example, hardware
300  * providers on UltraSPARC T2, n2rng(7d), ncp(7d), and n2cp(7d), each support
301  * only a single group of operations.
302  *

49 */
50
52 /*
53 * This is a generic 32 bit "collector" for message digest algorithms.
54 * Whenever needed it collects input character stream into chunks of
55 * 32 bit values and invokes a block function that performs actual hash
56 * calculations.
57 *
58 * Porting guide.
59 *
60 * Obligatory macros:
```

new/usr/src/lib/openssl/include/md32_common.h

2

```
62 * DATA_ORDER_IS_BIG_ENDIAN or DATA_ORDER_IS_LITTLE_ENDIAN
63 * this macro defines byte order of input stream.
64 * HASH_CBLOCK
65 * size of a unit chunk HASH_BLOCK operates on.
66 * HASH_LONG
67 * has to be at least 32 bit wide, if it's wider, then
68 * HASH_LONG_LOG2 "has to" be defined along
69 * HASH_CTX
70 * context structure that at least contains following
71 * members:
72 * typedef struct {
73 *     ...
74 *     HASH_LONG      Nl,Nh;
75 *     either {
76 *     HASH_LONG      data[HASH_LBLOCK];
77 *     unsigned char   data[HASH_CBLOCK];
78 *     };
79 *     unsigned int    num;
80 *     ...
81 * } HASH_CTX;
82 * data[] vector is expected to be zeroed upon first call to
83 * HASH_UPDATE.
84 * HASH_UPDATE
85 * name of "Update" function, implemented here.
86 * HASH_TRANSFORM
87 * name of "Transform" function, implemented here.
88 * HASH_FINAL
89 * name of "Final" function, implemented here.
90 * HASH_BLOCK_DATA_ORDER
91 * name of "block" function capable of treating *unaligned* input
92 * message in original (data) byte order, implemented externally.
93 * HASH_MAKE_STRING
94 * macro converging context variables to an ASCII hash string.
95 *
96 * MD5 example:
97 *
98 * #define DATA_ORDER_IS_LITTLE_ENDIAN
99 *
100 * #define HASH_LONG      MD5_LONG
101 * #define HASH_LONG_LOG2 MD5_LONG_LOG2
102 * #define HASH_CTX      MD5_CTX
103 * #define HASH_CBLOCK    MD5_CBLOCK
104 * #define HASH_UPDATE    MD5_Update
105 * #define HASH_TRANSFORM MD5_Transform
106 * #define HASH_FINAL     MD5_Final
107 * #define HASH_BLOCK_DATA_ORDER md5_block_data_order
108 *
109 * <appro@fy.chalmers.se>

387  * This comment was originally written for MD5, which is why it
388  * discusses A-D. But it basically applies to all 32-bit digests,
389  * which is why it was moved to common header file.

```

```
392 *
393 * In case you wonder why A-D are declared as long and not
394 * as MD5_LONG. Doing so results in slight performance
395 * boost on LP64 architectures. The catch is we don't
396 * really care if 32 MSBs of a 64-bit register get polluted
397 * with eventual overflows as we *save* only 32 LSBs in
398 * *either* case. Now declaring 'em long excuses the compiler
399 * from keeping 32 MSBs zeroed resulting in 13% performance
400 * improvement under SPARC Solaris7/64 and 5% under AlphaLinux.
401 * Well, to be honest it should say that this *prevents*
402 * performance degradation.
403 *                                     <appro@fy.chalmers.se>
404 */
405 #else
406 /*
407 * Above is not absolute and there are LP64 compilers that
408 * generate better code if MD32_REG_T is defined int. The above
409 * pre-processor condition reflects the circumstances under which
410 * the conclusion was made and is subject to further extension.

364 /* The following macros and typedefs allow an ASN1_ITEM
365  * to be embedded in a structure and referenced. Since
366  * the ASN1_ITEM pointers need to be globally accessible
367  * (possibly from shared libraries) they may exist in
368  * different forms. On platforms that support it the
369  * ASN1_ITEM structure itself will be globally exported.
370  * Other platforms will export a function that returns
371  * an ASN1_ITEM pointer.
372  *
373  * To handle both cases transparently the macros below
374  * should be used instead of hard coding an ASN1_ITEM
375  * pointer in a structure.
376  *
377  * The structure will look like this:
378  *
379  * typedef struct SOMETHING_st {
380  *     ...
381  *     ASN1_ITEM_EXP *iptr;
382  *     ...
383  * } SOMETHING;
384  *
385  * It would be initialised as e.g.:
386  *
387  * SOMETHING somevar = {...,ASN1_ITEM_ref(X509),...};
388  *
389  * and the actual pointer extracted with:
390  *
391  * const ASN1_ITEM *it = ASN1_ITEM_ptr(somevar.iptr);

```

```

392 *
393 * Finally an ASN1_ITEM pointer can be extracted from an
394 * appropriate reference with: ASN1_ITEM_rptr(x509). This
395 * would be used when a function takes an ASN1_ITEM * argument.
396 *

```

```

590 * For SEQUENCE types the templates field points
591 * to the members, the size field is the
592 * structure size.
593 *
594 * For CHOICE types the templates field points
595 * to each possible member (typically a union)
596 * and the 'size' field is the offset of the
597 * selector.
598 *
599 * The 'funcs' field is used for application
600 * specific functions.
601 *
602 * For COMPAT types the funcs field gives a
603 * set of functions that handle this type, this
604 * supports the old d2i, i2d convention.
605 *
606 * The EXTERN type uses a new style d2i/i2d.
607 * The new style should be used where possible
608 * because it avoids things like the d2i IMPLICIT
609 * hack.
610 *
611 * MSTRING is a multiple string type, it is used
612 * for a CHOICE of character strings where the
613 * actual strings all occupy an ASN1_STRING
614 * structure. In this case the 'utype' field
615 * has a special meaning, it is used as a mask
616 * of acceptable types using the B_ASN1 constants.
617 *
618 * NDEF_SEQUENCE is the same as SEQUENCE except
619 * that it will use indefinite length constructed
620 * encoding if requested.
621 *

705 #endif

707 /* Bignum consistency macros
708  * There is one "API" macro, bn_fix_top(), for stripping leading zeroes from
709  * bignum data after direct manipulations on the data. There is also an
710  * "internal" macro, bn_check_top(), for verifying that there are no leading
711  * zeroes. Unfortunately, some auditing is required due to the fact that
712  * bn_fix_top() has become an overabused duct-tape because bignum data is
713  * occasionally passed around in an inconsistent state. So the following
714  * changes have been made to sort this out;
715  * - bn_fix_top()'s implementation has been moved to bn_correct_top()
716  * - if BN_DEBUG isn't defined, bn_fix_top() maps to bn_correct_top(), and
717  *   bn_check_top() is as before.
718  * - if BN_DEBUG *is* defined;
719  *   - bn_check_top() tries to pollute unused words even if the bignum 'top' is
720  *     consistent. (ed: only if BN_DEBUG RAND is defined)
721  *   - bn_fix_top() maps to bn_check_top() rather than "fixing" anything.

```

```

722  * The idea is to have debug builds flag up inconsistent bignums when they
723  * occur. If that occurs in a bn_fix_top(), we examine the code in question; if
724  * the use of bn_fix_top() was appropriate (ie. it follows directly after code
725  * that manipulates the bignum) it is converted to bn_correct_top(), and if it
726  * was not appropriate, we convert it permanently to bn_check_top() and track
727  * down the cause of the bug. Eventually, no internal code should be using the
728  * bn_fix_top() macro. External applications and libraries should try this with
729  * their own code too, both in terms of building against the openssl headers
730  * with BN_DEBUG defined *and* linking with a version of OpenSSL built with it
731  * defined. This not only improves external code, it provides more test
732  * coverage for openssl's own code.
733  */

*****
1 /* crypto/des/des_old.h *- mode:C; c-file-style: "eay" *- */

3 /* WARNING WARNING WARNING WARNING WARNING WARNING WARNING WARNING
4 *
5 * The function names in here are deprecated and are only present to
6 * provide an interface compatible with openssl 0.9.6 and older as
7 * well as libdes. OpenSSL now provides functions where "des_" has
8 * been replaced with "DES_" in the names, to make it possible to
9 * make incompatible changes that are needed for C type security and
10 * other stuff.
11 *
12 * This include files has two compatibility modes:
13 *
14 * - If OPENSSL_DES_LIBDES_COMPATIBILITY is defined, you get an API
15 *   that is compatible with libdes and SLeay.
16 * - If OPENSSL_DES_LIBDES_COMPATIBILITY isn't defined, you get an
17 *   API that is compatible with OpenSSL 0.9.5x to 0.9.6x.
18 *
19 * Note that these modes break earlier snapshots of OpenSSL, where
20 * libdes compatibility was the only available mode or (later on) the
21 * preferred compatibility mode. However, after much consideration
22 * (and more or less violent discussions with external parties), it
23 * was concluded that OpenSSL should be compatible with earlier versions
24 * of itself before anything else. Also, in all honesty, libdes is
25 * an old beast that shouldn't really be used any more.
26 *
27 * Please consider starting to use the DES_ functions rather than the
28 * des_ ones. The des_ functions will disappear completely before
29 * OpenSSL 1.0!
30 *
