3 # =====
4 # Written by Andy Polyakov <appro@fy.chalmers.se> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # Version 2.1.
11 #
12 # aes-*-cbc benchmarks are improved by >70% [compared to gcc 3.3.2 on
13 # Opteron 240 CPU] plus all the bells-n-whistles from 32-bit version
14 # [you'll notice a lot of resemblance], such as compressed S-boxes
15 # in little-endian byte order, prefetch of these tables in CBC mode,
16 # as well as avoiding L1 cache aliasing between stack frame and key
17 # schedule and already mentioned tables, compressed Td4...
18 #
19 # Performance in number of cycles per processed byte for 128-bit key:
20 #
21 #           ECB encrypt      ECB decrypt      CBC large chunk
22 # AMD64      33              41              13.0
23 # EM64T      38              59              18.6(*)
24 # Core 2     30              43              14.5(*)
25 #
26 # (*) with hyper-threading off

3 # =====
4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # June 2011
11 #
12 # This is AESNI-CBC+SHA1 "stitch" implementation. The idea, as spelled
13 # in http://download.intel.com/design/intarch/papers/323686.pdf, is
14 # that since AESNI-CBC encrypt exhibit "very" low instruction-level
15 # parallelism, interleaving it with another algorithm would allow to
16 # utilize processor resources better and achieve better performance.
17 # SHA1 instruction sequences(*) are taken from sha1-x86_64.pl and
18 # AESNI code is weaved into it. Below are performance numbers in
19 # cycles per processed byte, less is better, for standalone AESNI-CBC
20 # encrypt, sum of the latter and standalone SHA1, and "stitched"
21 # subroutine:
22 #
23 #          AES-128-CBC    +SHA1          stitch    gain
24 # Westmere      3.77[+5.6]    9.37        6.65      +41%
25 # Sandy Bridge  5.05[+5.2(6.3)] 10.25(11.35) 6.16(7.08) +67%(+60%)
26 #
27 #          AES-192-CBC
28 # Westmere      4.51          10.11        6.97      +45%
29 # Sandy Bridge  6.05          11.25(12.35) 6.34(7.27) +77%(+70%)
30 #
31 #          AES-256-CBC
32 # Westmere      5.25          10.85        7.25      +50%
33 # Sandy Bridge  7.05          12.25(13.35) 7.06(7.70) +74%(+73%)
34 #
35 # (*) There are two code paths: SSE3 and AVX. See sha1-568.pl for
36 # background information. Above numbers in parentheses are SSE3
37 # results collected on AVX-capable CPU, i.e. apply on OSes that
38 # don't support AVX.
39 #
40 # Needless to mention that it makes no sense to implement "stitched"
41 # *decrypt* subroutine. Because *both* AESNI-CBC decrypt and SHA1
42 # fully utilize parallelism, so stitching would not give any gain
43 # anyway. Well, there might be some, e.g. because of better cache
44 # locality... For reference, here are performance results for
45 # standalone AESNI-CBC decrypt:
46 #
47 #          AES-128-CBC    AES-192-CBC    AES-256-CBC
48 # Westmere      1.31      1.55          1.80
49 # Sandy Bridge  0.93      1.06          1.22
50 #

191 # _aesni_[en|de]cryptN are private interfaces, N denotes interleave
192 # factor. Why 3x subroutine were originally used in loops? Even though
193 # aes[enc|dec] latency was originally 6, it could be scheduled only
194 # every *2nd* cycle. Thus 3x interleave was the one providing optimal
195 # utilization, i.e. when subroutine's throughput is virtually same as
196 # of non-interleaved subroutine [for number of input blocks up to 3].
197 # This is why it makes no sense to implement 2x subroutine.
198 # aes[enc|dec] latency in next processor generation is 8, but the
199 # instructions can be scheduled every cycle. Optimal interleave for
200 # new processor is therefore 8x, but it's unfeasible to accommodate it
201 # in XMM registers addressable in 32-bit mode and therefore 6x is
202 # used instead...

2 #
3 # =====
4 # Written by Andy Polyakov <appro@fy.chalmers.se> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # This module implements support for Intel AES-NI extension. In
11 # OpenSSL context it's used with Intel engine, but can also be used as
12 # drop-in replacement for crypto/aes/asm/aes-x86_64.pl [see below for
13 # details].
14 #
15 # Performance.
16 #
17 # Given aes(enc|dec) instructions' latency asymptotic performance for
18 # non-parallelizable modes such as CBC encrypt is 3.75 cycles per byte
19 # processed with 128-bit key. And given their throughput asymptotic
20 # performance for parallelizable modes is 1.25 cycles per byte. Being
21 # asymptotic limit it's not something you commonly achieve in reality,
22 # but how close does one get? Below are results collected for
23 # different modes and block sized. Pairs of numbers are for en-/
24 # decryption.
25 #
26 #      16-byte      64-byte      256-byte      1-KB      8-KB
27 # ECB  4.25/4.25    1.38/1.38    1.28/1.28    1.26/1.26    1.26/1.26
28 # CTR  5.42/5.42    1.92/1.92    1.44/1.44    1.28/1.28    1.26/1.26
29 # CBC  4.38/4.43    4.15/1.43    4.07/1.32    4.07/1.29    4.06/1.28
30 # CCM  5.66/9.42    4.42/5.41    4.16/4.40    4.09/4.15    4.06/4.07
31 # OFB  5.42/5.42    4.64/4.64    4.44/4.44    4.39/4.39    4.38/4.38
32 # CFB  5.73/5.85    5.56/5.62    5.48/5.56    5.47/5.55    5.47/5.55
33 #
34 # ECB, CTR, CBC and CCM results are free from EVP overhead. This means
35 # that otherwise used 'openssl speed -evp aes-128-??? -engine aesni
36 # [-decrypt]' will exhibit 10-15% worse results for smaller blocks.
37 # The results were collected with specially crafted speed.c benchmark
38 # in order to compare them with results reported in "Intel Advanced
39 # Encryption Standard (AES) New Instruction Set" White Paper Revision
40 # 3.0 dated May 2010. All above results are consistently better. This
41 # module also provides better performance for block sizes smaller than
42 # 128 bytes in points *not* represented in the above table.
43 #
44 # Looking at the results for 8-KB buffer.
45 #
46 # CFB and OFB results are far from the limit, because implementation
47 # uses "generic" CRYPTO_[c|o]fb128_encrypt interfaces relying on
48 # single-block aesni_encrypt, which is not the most optimal way to go.
49 # CBC encrypt result is unexpectedly high and there is no documented
50 # explanation for it. Seemingly there is a small penalty for feeding
51 # the result back to AES unit the way it's done in CBC mode. There is
52 # nothing one can do and the result appears optimal. CCM result is
53 # identical to CBC, because CBC-MAC is essentially CBC encrypt without
54 # saving output. CCM CTR "stays invisible," because it's neatly
55 # interleaved with CBC-MAC. This provides ~30% improvement over
56 # "straightforward" CCM implementation with CTR and CBC-MAC performed
57 # disjointly. Parallelizable modes practically achieve the theoretical
58 # limit.
59 #
60 # Looking at how results vary with buffer size.
61 #
```

new/usr/src/lib/openssl/libsunw_crypto/pl/aesni-x86_64.pl

2

```
62 # Curves are practically saturated at 1-KB buffer size. In most cases
63 # "256-byte" performance is >95%, and "64-byte" is ~90% of "8-KB" one.
64 # CTR curve doesn't follow this pattern and is "slowest" changing one
65 # with "256-byte" result being 87% of "8-KB." This is because overhead
66 # in CTR mode is most computationally intensive. Small-block CCM
67 # decrypt is slower than encrypt, because first CTR and last CBC-MAC
68 # iterations can't be interleaved.
69 #
70 # Results for 192- and 256-bit keys.
71 #
72 # EVP-free results were observed to scale perfectly with number of
73 # rounds for larger block sizes, i.e. 192-bit result being 10/12 times
74 # lower and 256-bit one - 10/14. Well, in CBC encrypt case differences
75 # are a tad smaller, because the above mentioned penalty biases all
76 # results by same constant value. In similar way function call
77 # overhead affects small-block performance, as well as OFB and CFB
78 # results. Differences are not large, most common coefficients are
79 # 10/11.7 and 10/13.4 (as opposite to 10/12.0 and 10/14.0), but one
80 # observe even 10/11.2 and 10/12.4 (CTR, OFB, CFB)...

82 # January 2011
83 #
84 # While Westmere processor features 6 cycles latency for aes[enc|dec]
85 # instructions, which can be scheduled every second cycle, Sandy
86 # Bridge spends 8 cycles per instruction, but it can schedule them
87 # every cycle. This means that code targeting Westmere would perform
88 # suboptimally on Sandy Bridge. Therefore this update.
89 #
90 # In addition, non-parallelizable CBC encrypt (as well as CCM) is
91 # optimized. Relative improvement might appear modest, 8% on Westmere,
92 # but in absolute terms it's 3.77 cycles per byte encrypted with
93 # 128-bit key on Westmere, and 5.07 - on Sandy Bridge. These numbers
94 # should be compared to asymptotic limits of 3.75 for Westmere and
95 # 5.00 for Sandy Bridge. Actually, the fact that they get this close
96 # to asymptotic limits is quite amazing. Indeed, the limit is
97 # calculated as latency times number of rounds, 10 for 128-bit key,
98 # and divided by 16, the number of bytes in block, or in other words
99 # it accounts *solely* for aesenc instructions. But there are extra
100 # instructions, and numbers so close to the asymptotic limits mean
101 # that it's as if it takes as little as *one* additional cycle to
102 # execute all of them. How is it possible? It is possible thanks to
103 # out-of-order execution logic, which manages to overlap post-
104 # processing of previous block, things like saving the output, with
105 # actual encryption of current block, as well as pre-processing of
106 # current block, things like fetching input and xor-ing it with
107 # 0-round element of the key schedule, with actual encryption of
108 # previous block. Keep this in mind...
109 #
110 # For parallelizable modes, such as ECB, CBC decrypt, CTR, higher
111 # performance is achieved by interleaving instructions working on
112 # independent blocks. In which case asymptotic limit for such modes
113 # can be obtained by dividing above mentioned numbers by AES
114 # instructions' interleave factor. Westmere can execute at most 3
115 # instructions at a time, meaning that optimal interleave factor is 3,
116 # and that's where the "magic" number of 1.25 come from. "Optimal
117 # interleave factor" means that increase of interleave factor does
118 # not improve performance. The formula has proven to reflect reality
119 # pretty well on Westmere... Sandy Bridge on the other hand can
120 # execute up to 8 AES instructions at a time, so how does varying
121 # interleave factor affect the performance? Here is table for ECB
122 # (numbers are cycles per byte processed with 128-bit key):
123 #
124 # instruction interleave factor      3x      6x      8x
125 # theoretical asymptotic limit      1.67    0.83    0.625
126 # measured performance for 8KB block  1.05    0.86    0.84
127 #
```

```

128 # "as if" interleave factor      4.7x   5.8x   6.0x
129 #
130 # Further data for other parallelizable modes:
131 #
132 # CBC decrypt      1.16   0.93   0.93
133 # CTR              1.14   0.91   n/a
134 #
135 # Well, given 3x column it's probably inappropriate to call the limit
136 # asymptotic, if it can be surpassed, isn't it? What happens there?
137 # Rewind to CBC paragraph for the answer. Yes, out-of-order execution
138 # magic is responsible for this. Processor overlaps not only the
139 # additional instructions with AES ones, but even AES instructions
140 # processing adjacent triplets of independent blocks. In the 6x case
141 # additional instructions still claim disproportionately small amount
142 # of additional cycles, but in 8x case number of instructions must be
143 # a tad too high for out-of-order logic to cope with, and AES unit
144 # remains underutilized... As you can see 8x interleave is hardly
145 # justifiable, so there no need to feel bad that 32-bit aesni-x86.pl
146 # utilizes 6x interleave because of limited register bank capacity.
147 #
148 # Higher interleave factors do have negative impact on Westmere
149 # performance. While for ECB mode it's negligible ~1.5%, other
150 # parallelizables perform ~5% worse, which is outweighed by ~25%
151 # improvement on Sandy Bridge. To balance regression on Westmere
152 # CTR mode was implemented with 6x aesenc interleave factor.

154 # April 2011
155 #
156 # Add aesni_xts_[en|de]crypt. Westmere spends 1.33 cycles processing
157 # one byte out of 8KB with 128-bit key, Sandy Bridge - 0.97. Just like
158 # in CTR mode AES instruction interleave factor was chosen to be 6x.

267 # _aesni_[en|de]cryptN are private interfaces, N denotes interleave
268 # factor. Why 3x subroutine were originally used in loops? Even though
269 # aes[enc|dec] latency was originally 6, it could be scheduled only
270 # every *2nd* cycle. Thus 3x interleave was the one providing optimal
271 # utilization, i.e. when subroutine's throughput is virtually same as
272 # of non-interleaved subroutine [for number of input blocks up to 3].
273 # This is why it makes no sense to implement 2x subroutine.
274 # aes[enc|dec] latency in next processor generation is 8, but the
275 # instructions can be scheduled every cycle. Optimal interleave for
276 # new processor is therefore 8x...

13 #####
14 #
15 # September 2011.
16 #
17 # Started as transliteration to "perlasm" the original code has
18 # undergone following changes:
19 #
20 # - code was made position-independent;
21 # - rounds were folded into a loop resulting in >5x size reduction
22 # from 12.5KB to 2.2KB;
23 # - above was possible thanks to mixcolumns() modification that
24 # allowed to feed its output back to aesenc[last], this was
25 # achieved at cost of two additional inter-registers moves;
26 # - some instruction reordering and interleaving;
27 # - this module doesn't implement key setup subroutine, instead it
28 # relies on conversion of "conventional" key schedule as returned
29 # by AES_set_encrypt_key (see discussion below);
30 # - first and last round keys are treated differently, which allowed
31 # to skip one shiftrows(), reduce bit-sliced key schedule and
32 # speed-up conversion by 22%;
33 # - support for 192- and 256-bit keys was added;
34 #
35 # Resulting performance in CPU cycles spent to encrypt one byte out
36 # of 4096-byte buffer with 128-bit key is:
37 #
38 #           Emilia's      this(*)      difference
39 #
40 # Core 2      9.30          8.69          +7%
41 # Nehalem(**) 7.63          6.98          +9%
42 # Atom       17.1          17.4          -2%(***)
43 #
44 # (*) Comparison is not completely fair, because "this" is ECB,
45 # i.e. no extra processing such as counter values calculation
46 # and xor-ing input as in Emilia's CTR implementation is
47 # performed. However, the CTR calculations stand for not more
48 # than 1% of total time, so comparison is *rather* fair.
49 #
50 # (**) Results were collected on Westmere, which is considered to
51 # be equivalent to Nehalem for this code.
52 #
53 # (***) Slowdown on Atom is rather strange per se, because original
54 # implementation has a number of 9+ bytes instructions, which
55 # are bad for Atom front-end, and which I eliminated completely.
56 # In attempt to address deterioration sbbox() was tested in FP
57 # SIMD "domain" (movaps instead of movdqa, xorps instead of
58 # pxor, etc.). While it resulted in nominal 4% improvement on
59 # Atom, it hurted Westmere by more than 2x factor.
60 #
61 # As for key schedule conversion subroutine. Interface to OpenSSL
```

new/usr/src/lib/openssl/libsunw_crypto/pl/bsaes-x86_64.pl

2

```
62 # relies on per-invocation on-the-fly conversion. This naturally
63 # has impact on performance, especially for short inputs. Conversion
64 # time in CPU cycles and its ratio to CPU cycles spent in 8x block
65 # function is:
66 #
67 #           conversion      conversion/8x block
68 # Core 2      240          0.22
69 # Nehalem     180          0.20
70 # Atom        430          0.19
71 #
72 # The ratio values mean that 128-byte blocks will be processed
73 # 16-18% slower, 256-byte blocks - 9-10%, 384-byte blocks - 6-7%,
74 # etc. Then keep in mind that input sizes not divisible by 128 are
75 # *effectively* slower, especially shortest ones, e.g. consecutive
76 # 144-byte blocks are processed 44% slower than one would expect,
77 # 272 - 29%, 400 - 22%, etc. Yet, despite all these "shortcomings"
78 # it's still faster than ["hyper-threading-safe" code path in]
79 # aes-x86_64.pl on all lengths above 64 bytes...
80 #
81 # October 2011.
82 #
83 # Add decryption procedure. Performance in CPU cycles spent to decrypt
84 # one byte out of 4096-byte buffer with 128-bit key is:
85 #
86 # Core 2      9.83
87 # Nehalem     7.74
88 # Atom       19.0
89 #
90 # November 2011.
91 #
92 # Add bsaes_xts_[en|de]crypt. Less-than-80-bytes-block performance is
93 # suboptimal, but XTS is meant to be used with larger blocks...
94 #
95 #                                     <appro@openssl.org>

27 #
28 # Pairs of numbers in "+" rows represent performance improvement over
29 # compiler generated position-independent code, PIC, and non-PIC
30 # respectively. PIC results are of greater relevance, as this module
31 # is position-independent, i.e. suitable for a shared library or PIE.
32 # Position independence "costs" one register, which is why compilers
33 # are so close with non-PIC results, they have an extra register to
34 # spare. CBC results are better than ECB ones thanks to "zero-copy"
35 # private _x86_* interface, and are ~30-40% better than with compiler
36 # generated cml1_cbc.o, and reach ~80-90% of x86_64 performance on
37 # same CPU (where applicable).

12 # =====

14 # Performance in cycles per processed byte (less is better) in
15 # 'openssl speed ...' benchmark:
16 #
17 #                               AMD64   Core2   EM64T
18 # -evp camellia-128-ecb      16.7     21.0    22.7
19 # + over gcc 3.4.6          +25%     +5%     0%
20 #
21 # camellia-128-cbc          15.7     20.4    21.1
22 #
23 # 128-bit key setup         128       216     205    cycles/key
24 # + over gcc 3.4.6          +54%    +39%    +15%
25 #
26 # Numbers in "+" rows represent performance improvement over compiler
27 # generated code. Key setup timings are impressive on AMD and Core2
28 # thanks to 64-bit operations being covertly deployed. Improvement on
29 # EM64T, pre-Core2 Intel x86_64 CPU, is not as impressive, because it
30 # apparently emulates some of 64-bit operations in [32-bit] microcode.

1312 # A question was risen about choice of vanilla MMX. Or rather why wasn't
1313 # SSE2 chosen instead? In addition to the fact that MMX runs on legacy
1314 # CPUs such as PIII, "4-bit" MMX version was observed to provide better
1315 # performance than *corresponding* SSE2 one even on contemporary CPUs.
1316 # SSE2 results were provided by Peter-Michael Hager. He maintains SSE2
1317 # implementation featuring full range of lookup-table sizes, but with
1318 # per-invocation lookup table setup. Latter means that table size is
1319 # chosen depending on how much data is to be hashed in every given call,
1320 # more data - larger table. Best reported result for Core2 is ~4 cycles
1321 # per processed byte out of 64KB block. This number accounts even for
1322 # 64KB table setup overhead. As discussed in gcm128.c we choose to be
1323 # more conservative in respect to lookup table sizes, but how do the
1324 # results compare? Minimalistic "256B" MMX version delivers ~11 cycles
1325 # on same platform. As also discussed in gcm128.c, next in line "8-bit
1326 # Shoup's" or "4KB" method should deliver twice the performance of
1327 # "256B" one, in other words not worse than ~6 cycles per byte. It
1328 # should be also be noted that in SSE2 case improvement can be "super-
1329 # linear," i.e. more than twice, mostly because >>8 maps to single

```

```

1330 # instruction on SSE2 register. This is unlike "4-bit" case when >>4
1331 # maps to same amount of instructions in both MMX and SSE2 cases.
1332 # Bottom line is that switch to SSE2 is considered to be justifiable
1333 # only in case we choose to implement "8-bit" method...

3 # =====
4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # March, June 2010
11 #
12 # The module implements "4-bit" GCM GHASH function and underlying
13 # single multiplication operation in GF(2^128). "4-bit" means that
14 # it uses 256 bytes per-key table [+128 bytes shared table]. GHASH
15 # function features so called "528B" variant utilizing additional
16 # 256+16 bytes of per-key storage [+512 bytes shared table].
17 # Performance results are for this streamed GHASH subroutine and are
18 # expressed in cycles per processed byte, less is better:
19 #
20 #             gcc 3.4.x(*)   assembler
21 #
22 # P4           28.6         14.0         +100%
23 # Opteron      19.3         7.7          +150%
24 # Core2        17.8         8.1(**)      +120%
25 #
26 # (*)   comparison is not completely fair, because C results are
27 #        for vanilla "256B" implementation, while assembler results
28 #        are for "528B";-)
29 # (**)  it's mystery [to me] why Core2 result is not same as for
30 #        Opteron;
31 #
32 # May 2010
33 #
34 # Add PCLMULQDQ version performing at 2.02 cycles per processed byte.
35 # See ghash-x86.pl for background information and details about coding
36 # techniques.
37 #
38 # Special thanks to David Woodhouse <dwmw2@infradead.org> for
39 # providing access to a Westmere-based system on behalf of Intel
40 # Open Source Technology Centre.
41 #

1 #!/usr/bin/env perl

3 # =====
4 # [Re]written by Andy Polyakov <appro@fy.chalmers.se> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====

10 # At some point it became apparent that the original SSLeay RC4
11 # assembler implementation performs suboptimally on latest IA-32
12 # microarchitectures. After re-tuning performance has changed as
13 # following:
14 #
15 # Pentium      -10%
16 # Pentium III  +12%
17 # AMD          +50% (*)
18 # P4           +250% (**)
19 #
20 # (*) This number is actually a trade-off:-) It's possible to
21 # achieve +72%, but at the cost of -48% off PIII performance.
22 # In other words code performing further 13% faster on AMD
23 # would perform almost 2 times slower on Intel PIII...
24 # For reference! This code delivers ~80% of rc4-amd64.pl
25 # performance on the same Opteron machine.
26 # (**) This number requires compressed key schedule set up by
27 # RC4_set_key [see commentary below for further details].
28 #
29 #                                     <appro@fy.chalmers.se>

31 # May 2011
32 #
33 # Optimize for Core2 and Westmere [and incidentally Opteron]. Current
34 # performance in cycles per processed byte (less is better) and
35 # improvement relative to previous version of this module is:
36 #
37 # Pentium      10.2                # original numbers
38 # Pentium III  7.8(*)
39 # Intel P4     7.5
40 #
41 # Opteron      6.1/+20%              # new MMX numbers
42 # Core2        5.3/+67% (**)
43 # Westmere     5.1/+94% (**)
44 # Sandy Bridge 5.0/+8%
45 # Atom         12.6/+6%
46 #
47 # (*) PIII can actually deliver 6.6 cycles per byte with MMX code,
48 # but this specific code performs poorly on Core2. And vice
49 # versa, below MMX/SSE code delivering 5.8/7.1 on Core2 performs
50 # poorly on PIII, at 8.0/14.5:-) As PIII is not a "hot" CPU
51 # [anymore], I chose to discard PIII-specific code path and opt
52 # for original IALU-only code, which is why MMX/SSE code path
53 # is guarded by SSE2 bit (see below), not MMX/SSE.
54 # (**) Performance vs. block size on Core2 and Westmere had a maximum
55 # at ... 64 bytes block size. And it was quite a maximum, 40-60%
56 # in comparison to largest 8KB block size. Above improvement
57 # coefficients are for the largest block size.

4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====

10 # June 2011
11 #
12 # This is RC4+MD5 "stitch" implementation. The idea, as spelled in
13 # http://download.intel.com/design/intarch/papers/323686.pdf, is that
14 # since both algorithms exhibit instruction-level parallelism, ILP,
15 # below theoretical maximum, interleaving them would allow to utilize
16 # processor resources better and achieve better performance. RC4
17 # instruction sequence is virtually identical to rc4-x86_64.pl, which
18 # is heavily based on submission by Maxim Perminov, Maxim Locktyukhin
19 # and Jim Guilford of Intel. MD5 is fresh implementation aiming to
20 # minimize register usage, which was used as "main thread" with RC4
21 # weaved into it, one RC4 round per one MD5 round. In addition to the
22 # stitched subroutine the script can generate standalone replacement
23 # md5_block_asm_data_order and RC4. Below are performance numbers in
24 # cycles per processed byte, less is better, for these the standalone
25 # subroutines, sum of them, and stitched one:
26 #
27 #
28 #      RC4      MD5      RC4+MD5  stitch  gain
29 # Opteron      6.5(*)   5.4      11.9    7.0   +70%(*)
30 # Core2         6.5     5.8      12.3    7.7   +60%
31 # Westmere      4.3     5.2       9.5    7.0   +36%
32 # Sandy Bridge  4.2     5.5       9.7    6.8   +43%
33 # Atom          9.3     6.5      15.8   11.1   +42%
34 #
35 # (*) rc4-x86_64.pl delivers 5.3 on Opteron, so real improvement
36 # is +53%...

37 my ($rc4,$md5)=(1,1); # what to generate?
38 my $D="#" if (!$md5); # if set to "#", MD5 is stitched into RC4(),
39 # but its result is discarded. Idea here is
40 # to be able to use 'openssl speed rc4' for
41 # benchmarking the stitched subroutine...

2 #
3 # =====
4 # Written by Andy Polyakov <appro@fy.chalmers.se> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # July 2004
11 #
12 # 2.22x RC4 tune-up:-) It should be noted though that my hand [as in
13 # "hand-coded assembler"] doesn't stand for the whole improvement
14 # coefficient. It turned out that eliminating RC4_CHAR from config
15 # line results in ~40% improvement (yes, even for C implementation).
16 # Presumably it has everything to do with AMD cache architecture and
17 # RAW or whatever penalties. Once again! The module *requires* config
18 # line *without* RC4_CHAR! As for coding "secret," I bet on partial
19 # register arithmetics. For example instead of 'inc %r8; and $255,%r8'
20 # I simply 'inc %r8b'. Even though optimization manual discourages
21 # to operate on partial registers, it turned out to be the best bet.
22 # At least for AMD... How IA32E would perform remains to be seen...

24 # November 2004
25 #
26 # As was shown by Marc Bevand reordering of couple of load operations
27 # results in even higher performance gain of 3.3x:-) At least on
28 # Opteron... For reference, 1x in this case is RC4_CHAR C-code
29 # compiled with gcc 3.3.2, which performs at ~54MBps per 1GHz clock.
30 # Latter means that if you want to *estimate* what to expect from
31 # *your* Opteron, then multiply 54 by 3.3 and clock frequency in GHz.

33 # November 2004
34 #
35 # Intel P4 EM64T core was found to run the AMD64 code really slow...
36 # The only way to achieve comparable performance on P4 was to keep
37 # RC4_CHAR. Kind of ironic, huh? As it's apparently impossible to
38 # compose blended code, which would perform even within 30% marginal
39 # on either AMD and Intel platforms, I implement both cases. See
40 # rc4_key.c for further details...

42 # April 2005
43 #
44 # P4 EM64T core appears to be "allergic" to 64-bit inc/dec. Replacing
45 # those with add/sub results in 50% performance improvement of folded
46 # loop...

48 # May 2005
49 #
50 # As was shown by Zou Nanhai loop unrolling can improve Intel EM64T
51 # performance by >30% [unlike P4 32-bit case that is]. But this is
52 # provided that loads are reordered even more aggressively! Both code
53 # paths, AMD64 and EM64T, reorder loads in essentially same manner
54 # as my IA-64 implementation. On Opteron this resulted in modest 5%
55 # improvement [I had to test it], while final Intel P4 performance
56 # achieves respectful 432MBps on 2.8GHz processor now. For reference.
57 # If executed on Xeon, current RC4_CHAR code-path is 2.7x faster than
58 # RC4_INT code-path. While if executed on Opteron, it's only 25%
59 # slower than the RC4_INT one [meaning that if CPU  $\mu$ -arch detection
60 # is not implemented, then this final RC4_CHAR code-path should be
61 # preferred, as it provides better *all-round* performance].

```

```

63 # March 2007
64 #
65 # Intel Core2 was observed to perform poorly on both code paths:- ( It
66 # apparently suffers from some kind of partial register stall, which
67 # occurs in 64-bit mode only [as virtually identical 32-bit loop was
68 # observed to outperform 64-bit one by almost 50%]. Adding two movzb to
69 # cloop1 boosts its performance by 80%! This loop appears to be optimal
70 # fit for Core2 and therefore the code was modified to skip cloop8 on
71 # this CPU.

73 # May 2010
74 #
75 # Intel Westmere was observed to perform suboptimally. Adding yet
76 # another movzb to cloop1 improved performance by almost 50%! Core2
77 # performance is improved too, but nominally...

79 # May 2011
80 #
81 # The only code path that was not modified is P4-specific one. Non-P4
82 # Intel code path optimization is heavily based on submission by Maxim
83 # Perminov, Maxim Locktyukhin and Jim Guilford of Intel. I've used
84 # some of the ideas even in attempt to optimize the original RC4_INT
85 # code path... Current performance in cycles per processed byte (less
86 # is better) and improvement coefficients relative to previous
87 # version of this module are:
88 #
89 # Opteron          5.3/+0%(*)
90 # P4                6.5
91 # Core2            6.2/+15%(**)
92 # Westmere         4.2/+60%
93 # Sandy Bridge     4.2/+120%
94 # Atom             9.3/+80%
95 #
96 # (*) But corresponding loop has less instructions, which should have
97 # positive effect on upcoming Bulldozer, which has one less ALU.
98 # For reference, Intel code runs at 6.8 cpb rate on Opteron.
99 # (**) Note that Core2 result is ~15% lower than corresponding result
100 # for 32-bit code, meaning that it's possible to improve it,
101 # but more than likely at the cost of the others (see rc4-586.pl
102 # to get the idea)...

392 #####
393 # The SSE3 implementation.
394 #
395 # %xmm[0-7] are used as ring @X[] buffer containing quadruples of last
396 # 32 elements of the message schedule or Xupdate outputs. First 4
397 # quadruples are simply byte-swapped input, next 4 are calculated
398 # according to method originally suggested by Dean Gaudet (modulo
399 # being implemented in SSE3). Once 8 quadruples or 32 elements are
400 # collected, it switches to routine proposed by Max Locktyukhin.
401 #
402 # Calculations inevitably require temporary registers, and there are
403 # no %xmm registers left to spare. For this reason part of the ring
404 # buffer, X[2..4] to be specific, is offloaded to 3 quadruples ring
405 # buffer on the stack. Keep in mind that X[2] is alias X[-6], X[3] -
406 # X[-5], and X[4] - X[-4]...
407 #
408 # Another notable optimization is aggressive stack frame compression
409 # aiming to minimize amount of 9-byte instructions...
410 #
411 # Yet another notable optimization is "jumping" $B variable. It means
412 # that there is no register permanently allocated for $B value. This
413 # allowed to eliminate one instruction from body_20_39...
414 #

3 # =====
4 # Written by Andy Polyakov <appro@fy.chalmers.se> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # sha1_block procedure for x86_64.
11 #
12 # It was brought to my attention that on EM64T compiler-generated code
13 # was far behind 32-bit assembler implementation. This is unlike on
14 # Opteron where compiler-generated code was only 15% behind 32-bit
15 # assembler, which originally made it hard to motivate the effort.
16 # There was suggestion to mechanically translate 32-bit code, but I
17 # dismissed it, reasoning that x86_64 offers enough register bank
18 # capacity to fully utilize SHA-1 parallelism. Therefore this fresh
19 # implementation:-) However! While 64-bit code does perform better
20 # on Opteron, I failed to beat 32-bit assembler on EM64T core. Well,
21 # x86_64 does offer larger *addressable* bank, but out-of-order core
22 # reaches for even more registers through dynamic aliasing, and EM64T
23 # core must have managed to run-time optimize even 32-bit code just as
24 # good as 64-bit one. Performance improvement is summarized in the
25 # following table:
26 #
27 #          gcc 3.4          32-bit asm          cycles/byte
28 # Opteron      +45%          +20%              6.8
29 # Xeon P4       +65%          +0%              9.9
30 # Core2        +60%          +10%             7.0
31 #
32 # August 2009.
33 #
34 # The code was revised to minimize code size and to maximize
35 # "distance" between instructions producing input to 'lea'
36 # instruction and the 'lea' instruction itself, which is essential
37 # for Intel Atom core.
38 #
39 # October 2010.
40 #
41 # Add SSSE3, Supplemental[!] SSE3, implementation. The idea behind it
42 # is to offload message schedule denoted by Wt in NIST specification,
43 # or Xupdate in OpenSSL source, to SIMD unit. See sha1-586.pl module
44 # for background and implementation details. The only difference from
45 # 32-bit code is that 64-bit code doesn't have to spill @X[] elements
46 # to free temporary registers.
47 #
48 # April 2011.
49 #
50 # Add AVX code path. See sha1-586.pl for further information.
51 #
52 #####
53 # Current performance is summarized in following table. Numbers are
54 # CPU clock cycles spent to process single byte (less is better).
55 #
56 #          x86_64          SSSE3          AVX
57 # P4          9.8          -
58 # Opteron     6.6          -
59 # Core2       6.7          6.1/+10%      -
60 # Atom       11.0         9.7/+13%      -
61 # Westmere   7.1          5.6/+27%      -
```

18 # SSE2 asm  -       -       38       24      20
19 # x86_64 asm(*) -     -       30      10.0    10.5
20 #
21 # (*) x86_64 assembler performance is presented for reference
22 # purposes.
23 #
24 # IALU code-path is optimized for elder Pentiums. On vanilla Pentium
25 # performance improvement over compiler generated code reaches ~60%,
26 # while on PIII - ~35%. On newer µ-archs improvement varies from 15%
27 # to 50%, but it's less important as they are expected to execute SSE2
28 # code-path, which is commonly ~2-3x faster [than compiler generated
29 # code]. SSE2 code-path is as fast as original sha512-sse2.pl, even
30 # though it does not use 128-bit operations. The latter means that
31 # SSE2-aware kernel is no longer required to execute the code. Another
32 # difference is that new code optimizes amount of writes, but at the
33 # cost of increased data cache "footprint" by 1/2KB.

9 # sha256/512_block procedure for x86_64.
10 #
11 # 40% improvement over compiler-generated code on Opteron. On EM64T
12 # sha256 was observed to run >80% faster and sha512 - >40%. No magical
13 # tricks, just straight implementation... I really wonder why gcc
14 # [being armed with inline assembler] fails to generate as fast code.
15 # The only thing which is cool about this module is that it's very
16 # same instruction sequence used for both SHA-256 and SHA-512. In
17 # former case the instructions operate on 32-bit operands, while in
18 # latter - on 64-bit ones. All I had to do is to get one flavor right,
19 # the other one passed the test right away:-)
20 #
21 # sha256_block runs in ~1005 cycles on Opteron, which gives you
22 # asymptotic performance of 64*1000/1005=63.7MBps times CPU clock
23 # frequency in GHz. sha512_block runs in ~1275 cycles, which results
24 # in 128*1000/1275=100MBps per GHz. Is there room for improvement?
25 # Well, if you compare it to IA-64 implementation, which maintains
26 # X[16] in register bank[!], tends to 4 instructions per CPU clock
27 # cycle and runs in 1003 cycles, 1275 is very good result for 3-way
28 # issue Opteron pipeline and X[16] maintained in memory. So that *if*
29 # there is a way to improve it, *then* the only way would be to try to
30 # offload X[16] updates to SSE unit, but that would require "deeper"
31 # loop unroll, which in turn would naturally cause size blow-up, not
32 # to mention increased complexity! And once again, only *if* it's
33 # actually possible to noticeably improve overall ILP, instruction
34 # level parallelism, on a given CPU implementation in this case.
35 #
36 # Special note on Intel EM64T. While Opteron CPU exhibits perfect
37 # performance ratio of 1.5 between 64- and 32-bit flavors [see above],
38 # [currently available] EM64T CPUs apparently are far from it. On the
39 # contrary, 64-bit version, sha512_block, is ~30% *slower* than 32-bit
40 # sha256_block:-( This is presumably because 64-bit shifts/rotates
41 # apparently are not atomic instructions, but implemented in microcode.

3 #####
4 ## Constant-time SSSE3 AES core implementation.
5 ## version 0.1
6 ##
7 ## By Mike Hamburg (Stanford University), 2009
8 ## Public domain.
9 ##
10 ## For details see http://shiftright.org/papers/vector_aes/ and
11 ## http://crypto.stanford.edu/vpaes/.

13 #####
14 # September 2011.
15 #
16 # Port vpaes-x86_64.pl as 32-bit "almost" drop-in replacement for
17 # aes-586.pl. "Almost" refers to the fact that AES_cbc_encrypt
18 # doesn't handle partial vectors (doesn't have to if called from
19 # EVP only). "Drop-in" implies that this module doesn't share key
20 # schedule structure with the original nor does it make assumption
21 # about its alignment...
22 #
23 # Performance summary. aes-586.pl column lists large-block CBC
24 # encrypt/decrypt/with-hyper-threading-off(*) results in cycles per
25 # byte processed with 128-bit key, and vpaes-x86.pl column - [also
26 # large-block CBC] encrypt/decrypt.
27 #
28 #               aes-586.pl               vpaes-x86.pl
29 #
30 # Core 2(**)    29.1/42.3/18.3            22.0/25.6(**)
31 # Nehalem       27.9/40.4/18.1            10.3/12.0
32 # Atom          102./119./60.1            64.5/85.3(**)
33 #
34 # (*) "Hyper-threading" in the context refers rather to cache shared
35 # among multiple cores, than to specifically Intel HTT. As vast
36 # majority of contemporary cores share cache, slower code path
37 # is common place. In other words "with-hyper-threading-off"
38 # results are presented mostly for reference purposes.
39 #
40 # (**) "Core 2" refers to initial 65nm design, a.k.a. Conroe.
41 #
42 # (***) Less impressive improvement on Core 2 and Atom is due to slow
43 # pshufb, yet it's respectable +32%/65% improvement on Core 2
44 # and +58%/40% on Atom (as implied, over "hyper-threading-safe"
45 # code path).
46 #
47 #
48 #               <appro@openssl.org>

4 ## Constant-time SSSE3 AES core implementation.
5 ## version 0.1
6 ##
7 ## By Mike Hamburg (Stanford University), 2009
8 ## Public domain.
9 ##
10 ## For details see http://shiftright.org/papers/vector_aes/ and
11 ## http://crypto.stanford.edu/vpaes/.

13 #####
14 # September 2011.
15 #
16 # Interface to OpenSSL as "almost" drop-in replacement for
17 # aes-x86_64.pl. "Almost" refers to the fact that AES_cbc_encrypt
18 # doesn't handle partial vectors (doesn't have to if called from
19 # EVP only). "Drop-in" implies that this module doesn't share key
20 # schedule structure with the original nor does it make assumption
21 # about its alignment...
22 #
23 # Performance summary. aes-x86_64.pl column lists large-block CBC
24 # encrypt/decrypt/with-hyper-threading-off(*) results in cycles per
25 # byte processed with 128-bit key, and vpaes-x86_64.pl column -
26 # [also large-block CBC] encrypt/decrypt.
27 #
28 #          aes-x86_64.pl          vpaes-x86_64.pl
29 #
30 # Core 2(**)    30.5/43.7/14.3    21.8/25.7(***)
31 # Nehalem      30.5/42.2/14.6     9.8/11.8
32 # Atom         63.9/79.0/32.1     64.0/84.8(***)
33 #
34 # (*) "Hyper-threading" in the context refers rather to cache shared
35 # among multiple cores, than to specifically Intel HTT. As vast
36 # majority of contemporary cores share cache, slower code path
37 # is common place. In other words "with-hyper-threading-off"
38 # results are presented mostly for reference purposes.
39 #
40 # (**) "Core 2" refers to initial 65nm design, a.k.a. Conroe.
41 #
42 # (***) Less impressive improvement on Core 2 and Atom is due to slow
43 # pshufb, yet it's respectable +40%/78% improvement on Core 2
44 # (as implied, over "hyper-threading-safe" code path).
45 #
46 #                                     <appro@openssl.org>

333     call     _vpaes_schedule_mangle # write output
334     jmp      .Loop_schedule_128

336 ##
337 ## .aes_schedule_192
338 ##
339 ## 192-bit specific part of key schedule.
340 ##
341 ## The main body of this schedule is the same as the 128-bit
342 ## schedule, but with more smearing. The long, high side is
343 ## stored in %xmm7 as before, and the short, low side is in
344 ## the high bits of %xmm6.
345 ##
346 ## This schedule is somewhat nastier, however, because each
347 ## round produces 192 bits of key material, or 1.5 round keys.
348 ## Therefore, on each cycle we do 2 rounds and produce 3 round
349 ## keys.
350 ##

2 #
3 # =====
4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # May 2011
11 #
12 # The module implements bn_GF2m_mul_2x2 polynomial multiplication used
13 # in bn_gf2m.c. It's kind of low-hanging mechanical port from C for
14 # the time being... Except that it has three code paths: pure integer
15 # code suitable for any x86 CPU, MMX code suitable for PIII and later
16 # and PCLMULQDQ suitable for Westmere and later. Improvement varies
17 # from one benchmark and µ-arch to another. Below are interval values
18 # for 163- and 571-bit ECDH benchmarks relative to compiler-generated
19 # code:
20 #
21 # PIII          16%-30%
22 # P4            12%-12%
23 # Opteron      18%-40%
24 # Core2        19%-44%
25 # Atom         38%-64%
26 # Westmere     53%-121%(PCLMULQDQ)/20%-32%(MMX)
27 # Sandy Bridge 72%-127%(PCLMULQDQ)/27%-23%(MMX)
28 #
29 # Note that above improvement coefficients are not coefficients for
30 # bn_GF2m_mul_2x2 itself. For example 120% ECDH improvement is result
31 # of bn_GF2m_mul_2x2 being >4x faster. As it gets faster, benchmark
32 # is more and more dominated by other subroutines, most notably by
33 # BN_GF2m_mod[_mul]_arr...

2 #
3 # =====
4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====
9 #
10 # May 2011
11 #
12 # The module implements bn_GF2m_mul_2x2 polynomial multiplication used
13 # in bn_gf2m.c. It's kind of low-hanging mechanical port from C for
14 # the time being... Except that it has two code paths: code suitable
15 # for any x86_64 CPU and PCLMULQDQ one suitable for Westmere and
16 # later. Improvement varies from one benchmark and µ-arch to another.
17 # Vanilla code path is at most 20% faster than compiler-generated code
18 # [not very impressive], while PCLMULQDQ - whole 85%-160% better on
19 # 163- and 571-bit ECDH benchmarks on Intel CPUs. Keep in mind that
20 # these coefficients are not ones for bn_GF2m_mul_2x2 itself, as not
21 # all CPU time is burnt in it...

3 # =====
4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====

10 # October 2005.
11 #
12 # Montgomery multiplication routine for x86_64. While it gives modest
13 # 9% improvement of rsa4096 sign on Opteron, rsa512 sign runs more
14 # than twice, >2x, as fast. Most common rsa1024 sign is improved by
15 # respectful 50%. It remains to be seen if loop unrolling and
16 # dedicated squaring routine can provide further improvement...

18 # July 2011.
19 #
20 # Add dedicated squaring procedure. Performance improvement varies
21 # from platform to platform, but in average it's ~5%/15%/25%/33%
22 # for 512-/1024-/2048-/4096-bit RSA *sign* benchmarks respectively.

24 # August 2011.
25 #
26 # Unroll and modulo-schedule inner loops in such manner that they
27 # are "fallen through" for input lengths of 8, which is critical for
28 # 1024-bit RSA *sign*. Average performance improvement in comparison
29 # to *initial* version of this module from 2005 is ~0%/30%/40%/45%
30 # for 512-/1024-/2048-/4096-bit RSA *sign* benchmarks respectively.

3 # =====
4 # Written by Andy Polyakov <appro@openssl.org> for the OpenSSL
5 # project. The module is, however, dual licensed under OpenSSL and
6 # CRYPTOGAMS licenses depending on where you obtain it. For further
7 # details see http://www.openssl.org/~appro/cryptogams/.
8 # =====

10 # August 2011.
11 #
12 # Companion to x86_64-mont.pl that optimizes cache-timing attack
13 # countermeasures. The subroutines are produced by replacing bp[i]
14 # references in their x86_64-mont.pl counterparts with cache-neutral
15 # references to powers table computed in BN_mod_exp_mont_consttime.
16 # In addition subroutine that scatters elements of the powers table
17 # is implemented, so that scatter-/gathering can be tuned without
18 # bn_exp.c modifications.

1 #!/usr/bin/env perl

3 # Ascetic x86_64 AT&T to MASM/NASM assembler translator by <appro>.
4 #
5 # Why AT&T to MASM and not vice versa? Several reasons. Because AT&T
6 # format is way easier to parse. Because it's simpler to "gear" from
7 # Unix ABI to Windows one [see cross-reference "card" at the end of
8 # file]. Because Linux targets were available first...
9 #
10 # In addition the script also "distills" code suitable for GNU
11 # assembler, so that it can be compiled with more rigid assemblers,
12 # such as Solaris /usr/ccs/bin/as.
13 #
14 # This translator is not designed to convert *arbitrary* assembler
15 # code from AT&T format to MASM one. It's designed to convert just
16 # enough to provide for dual-ABI OpenSSL modules development...
17 # There *are* limitations and you might have to modify your assembler
18 # code or this script to achieve the desired result...
19 #
20 # Currently recognized limitations:
21 #
22 # - can't use multiple ops per line;
23 #
24 # Dual-ABI styling rules.
25 #
26 # 1. Adhere to Unix register and stack layout [see cross-reference
27 # ABI "card" at the end for explanation].
28 # 2. Forget about "red zone," stick to more traditional blended
29 # stack frame allocation. If volatile storage is actually required
30 # that is. If not, just leave the stack as is.
31 # 3. Functions tagged with ".type name,@function" get crafted with
32 # unified Win64 prologue and epilogue automatically. If you want
33 # to take care of ABI differences yourself, tag functions as
34 # ".type name,@abi-omnipotent" instead.
35 # 4. To optimize the Win64 prologue you can specify number of input
36 # arguments as ".type name,@function,N." Keep in mind that if N is
37 # larger than 6, then you *have to* write "abi-omnipotent" code,
38 # because >6 cases can't be addressed with unified prologue.
39 # 5. Name local labels as .L*, do *not* use dynamic labels such as 1:
40 # (sorry about latter).
41 # 6. Don't use [or hand-code with .byte] "rep ret." "ret" mnemonic is
42 # required to identify the spots, where to inject Win64 epilogue!
43 # But on the pros, it's then prefixed with rep automatically:-)
44 # 7. Stick to explicit ip-relative addressing. If you have to use
45 # GOTPCREL addressing, stick to mov symbol@GOTPCREL(%rip),%r??
46 # Both are recognized and translated to proper Win64 addressing
47 # modes. To support legacy code a synthetic directive, .picmeup,
48 # is implemented. It puts address of the *next* instruction into
49 # target register, e.g.:
50 #
51 #             .picmeup      %rax
52 #             lea           .Label-.(%rax),%rax
53 #
54 # 8. In order to provide for structured exception handling unified
55 # Win64 prologue copies %rsp value to %rax. For further details
56 # see SEH paragraph at the end.
57 # 9. .init segment is allowed to contain calls to functions only.
58 # a. If function accepts more than 4 arguments *and* >4th argument
59 # is declared as non 64-bit value, do clear its upper part.

883 #
884 # (*) volatile register
885 # (-) preserved by callee
886 # (#) Nth argument, volatile
887 #
888 # In Unix terms top of stack is argument transfer area for arguments
889 # which could not be accommodated in registers. Or in other words 7th
890 # [integer] argument resides at 8(%rsp) upon function entry point.
891 # 128 bytes above %rsp constitute a "red zone" which is not touched
892 # by signal handlers and can be used as temporal storage without
893 # allocating a frame.
894 #
895 # In Win64 terms N*8 bytes on top of stack is argument transfer area,
896 # which belongs to/can be overwritten by callee. N is the number of
897 # arguments passed to callee, *but* not less than 4! This means that
898 # upon function entry point 5th argument resides at 40(%rsp), as well
899 # as that 32 bytes from 8(%rsp) can always be used as temporal
900 # storage [without allocating a frame]. One can actually argue that
901 # one can assume a "red zone" above stack pointer under Win64 as well.
902 # Point is that at apparently no occasion Windows kernel would alter
903 # the area above user stack pointer in true asynchronous manner...
904 #
905 # All the above means that if assembler programmer adheres to Unix
906 # register and stack layout, but disregards the "red zone" existence,
907 # it's possible to use following prologue and epilogue to "gear" from
908 # Unix to Win64 ABI in leaf functions with not more than 6 arguments.
909 #
910 # omnipotent_function:
911 # ifdef WIN64
912 #     movq    %rdi,8(%rsp)
913 #     movq    %rsi,16(%rsp)
914 #     movq    %rcx,%rdi    ; if 1st argument is actually present
915 #     movq    %rdx,%rsi    ; if 2nd argument is actually ...

928 #####
929 # Win64 SEH, Structured Exception Handling.
930 #
931 # Unlike on Unix systems(*) lack of Win64 stack unwinding information
932 # has undesired side-effect at run-time: if an exception is raised in
933 # assembler subroutine such as those in question (basically we're
934 # referring to segmentation violations caused by malformed input
935 # parameters), the application is briskly terminated without invoking
936 # any exception handlers, most notably without generating memory dump
937 # or any user notification whatsoever. This poses a problem. It's
938 # possible to address it by registering custom language-specific
939 # handler that would restore processor context to the state at
940 # subroutine entry point and return "exception is not handled, keep
941 # unwinding" code. Writing such handler can be a challenge... But it's
942 # doable, though requires certain coding convention. Consider following
943 # snippet:
944 #
945 # .type function,@function
946 # function:
947 #     movq    %rsp,%rax    # copy rsp to volatile register
948 #     pushq   %r15         # save non-volatile registers
949 #     pushq   %rbx
950 #     pushq   %rbp
951 #     movq    %rsp,%r11
952 #     subq    %rdi,%r11    # prepare [variable] stack frame
953 #     andq    $-64,%r11
954 #     movq    %rax,0(%r11) # check for exceptions
955 #     movq    %r11,%rsp    # allocate [variable] stack frame
956 #     movq    %rax,0(%rsp) # save original rsp value
957 # magic_point:
958 #     ...
959 #     movq    0(%rsp),%rcx # pull original rsp value
960 #     movq    -24(%rcx),%rbp # restore non-volatile registers
961 #     movq    -16(%rcx),%rbx
962 #     movq    -8(%rcx),%r15
963 #     movq    %rcx,%rsp    # restore original rsp
964 #     ret
965 # .size function,.-function
966 #
967 # The key is that up to magic_point copy of original rsp value remains
968 # in chosen volatile register and no non-volatile register, except for
969 # rsp, is modified. While past magic_point rsp remains constant till
970 # the very end of the function. In this case custom language-specific
971 # exception handler would look like this:
972 #
973 # EXCEPTION_DISPOSITION handler (EXCEPTION_RECORD *rec,ULONG64 frame,
974 #     CONTEXT *context,DISPATCHER_CONTEXT *disp)
975 # {
976 #     ULONG64 *rsp = (ULONG64 *)context->Rax;
977 #     if (context->Rip >= magic_point)
978 #     {
979 #         rsp = ((ULONG64 **)context->Rsp)[0];
980 #         context->Rbp = rsp[-3];
981 #         context->Rbx = rsp[-2];
982 #         context->R15 = rsp[-1];
983 #     }
984 #     context->Rsp = (ULONG64)rsp;
985 #     context->Rdi = rsp[1];
986 #     context->Rsi = rsp[2];
987 #
988 #     memcpy (disp->ContextRecord,context,sizeof(CONTEXT));
989 #     RtlVirtualUnwind(UNW_FLAG_NHANDLER,disp->ImageBase,
990 #         disp->ControlPc,disp->FunctionEntry,disp->ContextRecord,
991 #         &disp->HandlerData,&disp->EstablisherFrame,NULL);
992 #     return ExceptionContinueSearch;
993 # }
994 #
995 # It's appropriate to implement this handler in assembler, directly in

```

```

994 # function's module. In order to do that one has to know members'
995 # offsets in CONTEXT and DISPATCHER_CONTEXT structures and some constant
996 # values. Here they are:
997 #
998 #     CONTEXT.Rax           120
999 #     CONTEXT.Rcx           128
1000 #     CONTEXT.Rdx           136
1001 #     CONTEXT.Rbx           144
1002 #     CONTEXT.Rsp           152
1003 #     CONTEXT.Rbp           160
1004 #     CONTEXT.Rsi           168
1005 #     CONTEXT.Rdi           176
1006 #     CONTEXT.R8            184
1007 #     CONTEXT.R9            192
1008 #     CONTEXT.R10           200
1009 #     CONTEXT.R11           208
1010 #     CONTEXT.R12           216
1011 #     CONTEXT.R13           224
1012 #     CONTEXT.R14           232
1013 #     CONTEXT.R15           240
1014 #     CONTEXT.Rip           248
1015 #     CONTEXT.Xmm6          512
1016 #     sizeof(CONTEXT)       1232
1017 #     DISPATCHER_CONTEXT.ControlPc 0
1018 #     DISPATCHER_CONTEXT.ImageBase 8
1019 #     DISPATCHER_CONTEXT.FunctionEntry 16
1020 #     DISPATCHER_CONTEXT.EstablisherFrame 24
1021 #     DISPATCHER_CONTEXT.TargetIp 32
1022 #     DISPATCHER_CONTEXT.ContextRecord 40
1023 #     DISPATCHER_CONTEXT.LanguageHandler 48
1024 #     DISPATCHER_CONTEXT.HandlerData 56
1025 #     UNW_FLAG_NHANDLER 0
1026 #     ExceptionContinueSearch 1
1027 #
1028 # In order to tie the handler to the function one has to compose
1029 # couple of structures: one for .xdata segment and one for .pdata.
1030 #
1031 # UNWIND_INFO structure for .xdata segment would be
1032 #
1033 # function_unwind_info:
1034 #     .byte 9,0,0,0
1035 #     .rva handler
1036 #
1037 # This structure designates exception handler for a function with
1038 # zero-length prologue, no stack frame or frame register.
1039 #
1040 # To facilitate composing of .pdata structures, auto-generated "gear"
1041 # prologue copies rsp value to rax and denotes next instruction with
1042 # .LSEH_begin_{function_name} label. This essentially defines the SEH
1043 # styling rule mentioned in the beginning. Position of this label is
1044 # chosen in such manner that possible exceptions raised in the "gear"
1045 # prologue would be accounted to caller and unwound from latter's frame.
1046 # End of function is marked with respective .LSEH_end_{function_name}
1047 # label. To summarize, .pdata segment would contain
1048 #
1049 #     .rva .LSEH_begin_function
1050 #     .rva .LSEH_end_function
1051 #     .rva function_unwind_info
1052 #
1053 # Reference to function_unwind_info from .xdata segment is the anchor.
1054 # In case you wonder why references are 32-bit .rvas and not 64-bit
1055 # .quads. References put into these two segments are required to be
1056 # *relative* to the base address of the current binary module, a.k.a.
1057 # image base. No Win64 module, be it .exe or .dll, can be larger than
1058 # 2GB and thus such relative references can be and are accommodated in
1059 # 32 bits.

```

```

1060 #
1061 # Having reviewed the example function code, one can argue that "movq
1062 # %rsp,%rax" above is redundant. It is not! Keep in mind that on Unix
1063 # rax would contain an undefined value. If this "offends" you, use
1064 # another register and refrain from modifying rax till magic_point is
1065 # reached, i.e. as if it was a non-volatile register. If more registers
1066 # are required prior [variable] frame setup is completed, note that
1067 # nobody says that you can have only one "magic point." You can
1068 # "liberate" non-volatile registers by denoting last stack off-load
1069 # instruction and reflecting it in finer grade unwind logic in handler.
1070 # After all, isn't it why it's called *language-specific* handler...
1071 #
1072 # Attentive reader can notice that exceptions would be mishandled in
1073 # auto-generated "gear" epilogue. Well, exception effectively can't
1074 # occur there, because if memory area used by it was subject to
1075 # segmentation violation, then it would be raised upon call to the
1076 # function (and as already mentioned be accounted to caller, which is
1077 # not a problem). If you're still not comfortable, then define tail
1078 # "magic point" just prior ret instruction and have handler treat it...
1079 #
1080 # (*) Note that we're talking about run-time, not debug-time. Lack of
1081 # unwind information makes debugging hard on both Windows and
1082 # Unix. "Unlike" refers to the fact that on Unix signal handler
1083 # will always be invoked, core dumped and appropriate exit code
1084 # returned to parent (for user notification).

```

new/usr/src/lib/openssl/libsunw_crypto/rand/rand_egd.c

2

```
62 * Query the EGD <URL: http://www.lothar.com/tech/crypto/>.
63 *
64 * This module supplies three routines:
65 *
66 * RAND_query_egd_bytes(path, buf, bytes)
67 * will actually query "bytes" bytes of entropy from the egd-socket located
68 * at path and will write them to buf (if supplied) or will directly feed
69 * it to RAND_seed() if buf==NULL.
70 * The number of bytes is not limited by the maximum chunk size of EGD,
71 * which is 255 bytes. If more than 255 bytes are wanted, several chunks
72 * of entropy bytes are requested. The connection is left open until the
73 * query is completed.
74 * RAND_query_egd_bytes() returns with
75 * -1 if an error occurred during connection or communication.
76 * num the number of bytes read from the EGD socket. This number is either
77 * the number of bytes requested or smaller, if the EGD pool is
78 * drained and the daemon signals that the pool is empty.
79 * This routine does not touch any RAND_status(). This is necessary, since
80 * PRNG functions may call it during initialization.
81 *
82 * RAND_egd_bytes(path, bytes) will query "bytes" bytes and have them
83 * used to seed the PRNG.
84 * RAND_egd_bytes() is a wrapper for RAND_query_egd_bytes() with buf=NULL.
85 * Unlike RAND_query_egd_bytes(), RAND_status() is used to test the
86 * seed status so that the return value can reflect the seed state:
87 * -1 if an error occurred during connection or communication _or_
88 * if the PRNG has still not received the required seeding.
89 * num the number of bytes read from the EGD socket. This number is either
90 * the number of bytes requested or smaller, if the EGD pool is
91 * drained and the daemon signals that the pool is empty.
92 *
93 * RAND_egd(path) will query 255 bytes and use the bytes retrieved to seed
94 * the PRNG.
95 * RAND_egd() is a wrapper for RAND_egd_bytes() with numbytes=255.

219     /* VMS NOTE: Prior versions of this routine created a _new_
220     * version of the rand file for each call into this routine, then
221     * deleted all existing versions named ; -1, and finally renamed
222     * the current version as ;1'. Under concurrent usage, this
223     * resulted in an RMS race condition in rename() which could
224     * orphan files (see vms message help for RMSS_REENT). With the
225     * fopen() calls below, openssl/VMS now shares the top-level
226     * version of the rand file. Note that there may still be
227     * conditions where the top-level rand file is locked. If so, this
228     * code will then create a new version of the rand file. Without
229     * the delete and rename code, this can result in ascending file
230     * versions that stop at version 32767, and this routine will then
231     * return an error. The remedy for this is to recode the calling
232     * application to avoid concurrent use of the rand file, or
233     * synchronize usage at the application level. Also consider
234     * whether or not you NEED a persistent rand file in a concurrent
235     * use situation.

10  * IMPLEMENTATION NOTES.
11  *
12  * As you might have noticed 32-bit hash algorithms:
13  *
14  * - permit SHA_LONG to be wider than 32-bit (case on CRAY);
15  * - optimized versions implement two transform functions: one operating
16  *   on [aligned] data in host byte order and one - on data in input
17  *   stream byte order;
18  * - share common byte-order neutral collector and padding function
19  *   implementations, ../md32_common.h;
20  *
21  * Neither of the above applies to this SHA-512 implementations. Reasons
22  * [in reverse order] are:
23  *
24  * - it's the only 64-bit hash algorithm for the moment of this writing,
25  *   there is no need for common collector/padding implementation [yet];
26  * - by supporting only one transform function [which operates on
27  *   *aligned* data in input stream byte order, big-endian in this case]
28  *   we minimize burden of maintenance in two ways: a) collector/padding
29  *   function is simpler; b) only one transform function to stare at;
30  * - SHA_LONG64 is required to be exactly 64-bit in order to be able to
31  *   apply a number of optimizations to mitigate potential performance
32  *   penalties caused by previous design decision;
33  *
34  * Caveat lector.
35  *
36  * Implementation relies on the fact that "long long" is 64-bit on
37  * both 32- and 64-bit platforms. If some compiler vendor comes up
38  * with 128-bit long long, adjustment to sha.h would be required.
39  * As this implementation relies on 64-bit integer type, it's totally
40  * inappropriate for platforms which don't support it, most notably
41  * 16-bit platforms.
42  *
43  *                                     <appro@fy.chalmers.se>
