 *      Then
 *              1/m0 is looked up in a table of 1, 1/(1+1/128), ..., 1/(1+128/12
 *              256*log2(m0) is looked up in a table of 256*log2(1), 256*log2(1+
 *                      ..., 256*log2(1+128/128).
 *              256*log2(1+z) is computed using approximation:
 *                      256*log2(1+z) = (((a3*z + a2)*z + a1)*z + a0)*z.
 *      3. For w >= 32768
 *              then for (negative) ** (odd integer)            => -Inf + overfl
 *              else                                            => +Inf + overfl
 *      For w <= -38400
 *              then for (negative) ** (odd integer)            => -0 + underflo
 *              else                                            => +0 + underflo
 *      4. Computes 2 ** (w/256) from:
 *              2 ** (w/256) = 2**a  *  2**(k/256)  *  2**(r/256)
 *      Where:
 *              a    =    int  ( w ) >> 8;
 *              k    =    int  ( w ) & 0xFF;
 *              r    =    frac ( w ).
 *      Note that:
 *              k = 0, 1, ..., 255;
 *              r = (-1, 1).
 *      Then:
 *              2**(k/256) is looked up in a table of 2**0, 2**1/256, ...
 *              2**(r/256) is computed using approximation:
 *                      2**(r/256) =  a0 + a1 * r + a2 * r**2
 *              Multiplication by 2**a is done by adding "a" to
 *              the biased exponent.
 *      5. For (negative) ** (odd integer)      => -(2**(w/256))
 *      otherwise                               =>   2**(w/256)
 *
 * Accuracy:
 *      Max. relative aproximation error < 2**(-37.35) for 256*log2(1+z).
 *      Max. relative aproximation error < 2**(-29.18) for 2**(r/256).
 *      All calculations are done in double precision.
 *      Maximum error observed: less than 0.528 ulp after 700.000.000
 *      results.

/*
 * Given X, __vlibm_rem_pio2m finds Y and an integer n such that
 * Y = X - n*pi/2 and |Y| < pi/2.
 *
 * On entry, X is represented by x, an array of nx 24-bit integers
 * stored in double precision format, and e:
 *
 *   X = sum (x[i] * 2^(e - 24*i))
 *
 * nx must be 1, 2, or 3, and e must be >= -24.  For example, a
 * suitable representation for the double precision number z can
 * be computed as follows:
 *
 *      e  = ilogb(z)-23
 *      z  = scalbn(z,-e)
 *      for i = 0,1,2
 *              x[i] = floor(z)
 *              z    = (z-x[i])*2**24
 *
 * On exit, Y is approximated by y[0] if prec is 0 and by the un-
 * evaluated sum y[0] + y[1] if prec != 0.  The approximation is
 * accurate to 53 bits in the former case and to at least 72 bits
 * in the latter.
 *
 * __vlibm_rem_pio2m returns n mod 8.
 *
 * Notes:
 *
 * As n is the integer nearest X * 2/pi, we approximate the latter
 * product to a precision that is determined dynamically so as to
 * ensure that the final value Y is approximated accurately enough.
 * We don't bother to compute terms in the product that are multiples
```

```
 * of 8, so the cost of this multiplication is independent of the
 * magnitude of X.  The variable ip determines the offset into the
 * array ipio2 of the first term we need to use.  The variable eq0
 * is the corresponding exponent of the first partial product.
 *
 * The partial products are scaled, summed, and split into an array
 * of non-overlapping 24-bit terms (not necessarily having the same
 * signs).  Each partial product overlaps three elements of the
 * resulting array:
 *
 *      q[i]   xxxxxxxxxxxxxx
 *      q[i+1]       xxxxxxxxxxxxxx
 *      q[i+2]             xxxxxxxxxxxxxx
 *      ...                      ...
 *
 *
 *      r[i]     xxxxxx
 *      r[i+1]         xxxxxx
 *      r[i+2]               xxxxxx
 *      ...                        ...
 *
 * In order that the last element of the r array have some correct
 * bits, we compute an extra term in the q array, but we don't bother
 * to split this last term into 24-bit chunks; thus, the final term
 * of the r array could have more than 24 bits, but this doesn't
 * matter.
 *
 * After we subtract the nearest integer to the product, we multiply
 * the remaining part of r by pi/2 to obtain Y.  Before we compute
 * this last product, however, we make sure that the remaining part
 * of r has at least five nonzero terms, computing more if need be.
 * This ensures that even if the first nonzero term is only a single
 * bit and the last term is wrong in several trailing bits, we still
 * have enough accuracy to obtain 72 bits of Y.
 *
 * IMPORTANT: This code assumes that the rounding mode is round-to-
 * nearest in several key places.  First, after we compute X * 2/pi,
 * we round to the nearest integer by adding and subtracting a power
 * of two.  This step must be done in round-to-nearest mode to ensure
 * that the remainder is less than 1/2 in absolute value.  (Because
 * we only take two adjacent terms of r into account when we perform
 * this rounding, in very rare cases the remainder could be just
 * barely greater than 1/2, but this shouldn't matter in practice.)
 *
 * Second, we also split the partial products of X * 2/pi into 24-bit
 * pieces by adding and subtracting a power of two.  In this step,
 * round-to-nearest mode is important in order to guarantee that
 * the index of the first nonzero term in the remainder gives an
 * accurate indication of the number of significant terms.  For
 * example, suppose eq0 = -1, so that r[1] is a multiple of 1/2 and
 * |r[2]| < 1/2.  After we subtract the nearest integer, r[1] could
 * be -1/2, and r[2] could be very nearly 1/2, so that r[1] != 0,
 * yet the remainder is much smaller than the least significant bit
 * corresponding to r[1].  As long as we use round-to-nearest mode,
 * this can't happen; instead, the absolute value of each r[j] will
 * be less than 1/2 the least significant bit corresponding to r[j-1],
 * so that the entire remainder must be at least half as large as
 * the first nonzero term (or perhaps just barely smaller than this).

/* float rhypotf(float x, float y)
 *
 * Method :
 *      1. Special cases:
 *              for x or y = Inf                        => 0;
 *              for x or y = NaN                        => QNaN;
 *              for x and y = 0                         => +Inf + divide-by-zero
 *      2. Computes d = x * x + y * y;
 *      3. Computes reciprocal square root from:
 *              d = m * 2**n
 *      Where:
 *              m = [0.5, 2),
 *              n = ((exponent + 1) & ~1).
 *      Then:
```

```
 *              rsqrtf(d) = 1/sqrt( m * 2**n ) = (2 ** (-n/2)) * (1/sqrt(m))
 *      4. Computes 1/sqrt(m) from:
 *              1/sqrt(m) = (1/sqrt(m0)) * (1/sqrt(1 + (1/m0)*dm))
 *      Where:
 *              m = m0 + dm,
 *              m0 = 0.5 * (1 + k/64) for m = [0.5,         0.5+127/256), k = [0
 *              m0 = 1.0 * (0 + k/64) for m = [0.5+127/256, 1.0+127/128), k = [6
 *      Then:
 *              1/sqrt(m0), 1/m0 are looked up in a table,
 *              1/sqrt(1 + (1/m0)*dm) is computed using approximation:
 *                      1/sqrt(1 + z) = ((a3 * z + a2) * z + a1) * z + a0
 *                      where z = [-1/64, 1/64].
 *
 * Accuracy:
 *      The maximum relative error for the approximating
 *      polynomial is 2**(-27.87).
 *      Maximum error observed: less than 0.535 ulp after 3.000.000.000
 *      results.
 */

/* double rsqrt(double x)
 *
 * Method :
 *      1. Special cases:
 *              for x = NaN                             => QNaN;
 *              for x = +Inf                            => 0;
 *              for x is negative, -Inf                 => QNaN + invalid;
 *              for x = +0                              => +Inf + divide-by-zero
 *              for x = -0                              => -Inf + divide-by-zero
 *      2. Computes reciprocal square root from:
 *              x = m * 2**n
 *      Where:
 *              m = [0.5, 2),
 *              n = ((exponent + 1) & ~1).
```

```
 *      Then:
 *              rsqrt(x) = 1/sqrt( m * 2**n ) = (2 ** (-n/2)) * (1/sqrt(m))
 *      2. Computes 1/sqrt(m) from:
 *              1/sqrt(m) = (1/sqrt(m0)) * (1/sqrt(1 + (1/m0)*dm))
 *      Where:
 *              m = m0 + dm,
 *              m0 = 0.5 * (1 + k/64) for m = [0.5,         0.5+127/256), k = [0
 *              m0 = 1.0 * (0 + k/64) for m = [0.5+127/256, 1.0+127/128), k = [6
 *              m0 = 2.0              for m = [1.0+127/128, 2.0),         k = 12
 *      Then:
 *              1/sqrt(m0) is looked up in a table,
 *              1/m0 is computed as (1/sqrt(m0)) * (1/sqrt(m0)).
 *              1/sqrt(1 + (1/m0)*dm) is computed using approximation:
 *                      1/sqrt(1 + z) = (((((a6 * z + a5) * z + a4) * z + a3)
 *                                                      * z + a2) * z + a1) * z + a0
 *                      where z = [-1/128, 1/128].
 *
 * Accuracy:
 *      The maximum relative error for the approximating
 *      polynomial is 2**(-56.26).
 *      Maximum error observed: less than 0.563 ulp after 1.500.000.000
 *      results.
 */

/* float rsqrtf(float x)
 *
 * Method :
 *      1. Special cases:
 *              for x = NaN                             => QNaN;
 *              for x = +Inf                            => 0;
 *              for x is negative, -Inf                 => QNaN + invalid;
 *              for x = +0                              => +Inf + divide-by-zero
 *              for x = -0                              => -Inf + divide-by-zero
 *      2. Computes reciprocal square root from:
 *              x = m * 2**n
 *      Where:
 *              m = [0.5, 2),
 *              n = ((exponent + 1) & ~1).
 *      Then:
 *              rsqrtf(x) = 1/sqrt( m * 2**n ) = (2 ** (-n/2)) * (1/sqrt(m))
 *      2. Computes 1/sqrt(m) from:
 *              1/sqrt(m) = (1/sqrt(m0)) * (1/sqrt(1 + (1/m0)*dm))
 *      Where:
 *              m = m0 + dm,
 *              m0 = 0.5 * (1 + k/64) for m = [0.5,         0.5+127/256), k = [0
 *              m0 = 1.0 * (0 + k/64) for m = [0.5+127/256, 1.0+127/128), k = [6
 *      Then:
```

```
 *              1/sqrt(m0), 1/m0 are looked up in a table,
 *              1/sqrt(1 + (1/m0)*dm) is computed using approximation:
 *                      1/sqrt(1 + z) = ((a3 * z + a2) * z + a1) * z + a0
 *                      where z = [-1/64, 1/64].
 *
 * Accuracy:
 *      The maximum relative error for the approximating
 *      polynomial is 2**(-27.87).
 *      Maximum error observed: less than 0.534 ulp for the
 *      whole float type range.
 */

#include "libm.h"

        RO_DATA

/*********************************************************************
 * vexp() algorithm is from mopt:f_exp.c.  Basics are included here
 * to supplement comments within this file.  vexp() has been unrolled
 * to a depth of 3.  Only element 0 is documented.
 *
 * Note 1: INVLN2_256, LN2_256H, and LN2_256L were originally scaled by
 *      2^44 to allow *2^k w/o shifting within the FP registers.  These
 *      had to be removed for CHEETAH to avoid the fdtox of a very large
 *      number, which would trap to kernel (2^52).
 *
 * Let  x = (k + j/256)ln2 + r
 * then exp(x) = exp(ln2^(k+j/256)) * exp(r)
 *             = 2^k * 2^(j/256) * exp(r)
 * where r is polynomial approximation
 *      exp(r) = 1 + r + r^2*B1 + r^3*B2 + r^4*B3
 *             = 1 + r*(1+r*(B1+r*(B2+r*B3)))
 *      let
 *      p = r*(1+r*(B1+r*(B2+r*B3)))    ! notice, not quite exp(r)
 *      q = 2^(j/256) (high 64 bits)
 *      t = 2^(j/256) (extra precision) ! both from _TBL_exp_z[]
 *      then
 *      2^(j/256) * exp(r) = (q+t)(1+p) ~ q + ( t + q*p )
 *      then actual computation is 2^k * ( q + ( t + q*p ) )
 *
 *********************************************************************/

484 ! Once we get to the last element, we loop three more times to finish
485 ! the computations in progress.  This means we will load past the end
486 ! of the argument vector, but since we use non-faulting loads and never
487 ! use the data, the only potential problem is cache miss.  (Note that
488 ! when the argument is 2, the only exception that occurs in the compu-
489 ! tation is an inexact result in the final addition, and we break out
490 ! of the "extra" iterations before then.)

.TH acos 3M "12 Jul 2006" "SunOS 5.11" "Mathematical Library Functions"
.SH NAME
acos, acosf, acosl \- arc cosine functions
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBacos\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBfloat\fR \fBacosf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBlong double\fR \fBacosl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the principal value of the arc cosine of \fIx\fR. The
value of \fIx\fR should be in the range [\(mi1,1].
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the arc cosine of \fIx\fR in
the range [0, \c
.if n pi\c
.if t \(*p
\c
] radians.
.sp
.LP
For finite values of  \fIx\fR not in the range [\(mi1,1], a domain error occurs
and NaN is returned.
.sp
.LP
If \fIx\fR is NaN, NaN is returned.
.sp
.LP
If \fIx\fR is +1, +0 is returned.
.sp
.LP
If \fIx\fR is \(+-Inf, a domain error occurs and NaN is returned.
.sp
```

```
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBacos()\fR as specified by SVID3 and XPG3.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is finite and not in the range [-1,1], or is \(+-Inf.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.sp
The \fBacos()\fR function sets \fBerrno\fR to \fBEDOM\fR if \fIx\fR is not
\(+-Inf or NaN and is not in the range [\(mi1,1].
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBacos()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBacosf()\fR
and \fBacosl()\fR functions do not set \fBerrno\fR.
.SH ATTRIBUTES
.sp

.SH NAME
acosh, acoshf, acoshl \- inverse hyperbolic cosine functions
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBacosh\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBfloat\fR \fBacoshf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBlong double\fR \fBacoshl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the inverse hyperbolic cosine of their argument
\fIx\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the inverse hyperbolic
cosine of their argument.
.sp
.LP
For finite values of  \fIx\fR < 1, a domain error occurs and NaN is returned.
.sp
.LP
If \fIx\fR is NaN, NaN is returned.
.sp
.LP
If \fIx\fR is +1, +0 is returned.
.sp
.LP
If \fIx\fR is +Inf, +Inf is returned.
.sp
.LP
If \fIx\fR is \(miInf, a domain error occurs and NaN is returned.
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBacosh()\fR as specified by SVID3 and XPG3.
.SH ERRORS
```

```
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is finite and less than 1.0, or is \(miInf.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.sp
The \fBacosh()\fR function sets \fBerrno\fR to \fBEDOM\fR if \fIx\fR is less
than 1.0.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBacosh()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBacoshf()\fR
and \fBacoshl()\fR functions do not set \fBerrno\fR.

.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the inverse hyperbolic tangent of their argument
\fIx\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the inverse hyperbolic
tangent of their argument.
.sp
.LP
If \fIx\fR is \(+-1, a pole error occurs and \fBatanh()\fR, \fBatanhf()\fR, and
\fBatanhl()\fR return the value of the macro \fBHUGE_VAL\fR, \fBHUGE_VALF\fR,
and \fBHUGE_VALL\fR, respectively, with the same sign as the correct value of
the function.
.sp
.LP
For finite |\fIx\fR| > 1, a domain error occurs and a NaN is returned.
.sp
.LP
If \fIx\fR is NaN, NaN is returned.
.sp
.LP
If \fIx\fR is +0, \fIx\fR is returned.
.sp
.LP
If \fIx\fR is +Inf, a domain error occurs and a NaN is returned.
```

```
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBatanh()\fR as specified by SVID3 and XPG3.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is finite and not in the range [-1,1], or is \(+-Inf.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.sp
The \fBatanh()\fR function sets \fBerrno\fR to \fBEDOM\fR if the absolute value
of \fIx\fR is greater than 1.0.
.RE

.sp
.ne 2
.mk
.na
\fBPole Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is \(+-1.
.sp
If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then
the divide-by-zero floating-point exception is raised.
.sp
The \fBatanh()\fR function sets \fBerrno\fR to \fBERANGE\fR if the absolute
value of \fIx\fR is equal to 1.0.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBatanh()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBatanhf()\fR
and \fBatanhl()\fR functions do not set \fBerrno\fR.

\fBfloat\fR \fBceilf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBlong double\fR \fBceill\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the smallest integral value not less than \fIx\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, the \fBceil()\fR, \fBceilf()\fR, and \fBceill()\fR
functions return the smallest integral value not less than \fIx\fR, expressed
as a type \fBdouble\fR, \fBfloat\fR, or \fBlong double\fR, respectively.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0 or \(+-Inf, \fIx\fR is returned.
.SH USAGE
.sp
.LP
The integral value returned by these functions need not be expressible as an
\fBint\fR or \fBlong int\fR. The return value should be tested before assigning
it to an integer type to avoid the undefined results of an integer overflow.

.SH DESCRIPTION
.sp
.LP
These functions compute the cosine of \fIx\fR, measured in radians.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the cosine of \fIx\fR.
.sp
.LP
If \fIx\fR is NaN, NaN is returned.
.sp
.LP
If \fIx\fR is +0, 1.0 is returned.
.sp
.LP
If \fIx\fR is \(+-Inf, a domain error occurs and a NaN is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
```

```
.rt
The \fIx\fR argument is \(+-Inf.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.SH NAME
cosh, coshf, coshl \- hyperbolic cosine function
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBcosh\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBfloat\fR \fBcoshf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBlong double\fR \fBcoshl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the hyperbolic cosine of their argument \fIx\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the hyperbolic cosine of
\fIx\fR.
.sp
.LP
If the correct value would cause overflow, a range error occurs and
\fBcosh()\fR, \fBcoshf()\fR, and \fBcoshl()\fR return the value of the macro
\fBHUGE_VAL\fR, \fBHUGE_VALF\fR, and \fBHUGE_VALL\fR, respectively.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0, 1.0 is returned.
.sp
.LP
If \fIx\fR is \(+-Inf, \(+-Inf is returned.
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBcosh()\fR as specified by SVID3 and XPG3.
.SH ERRORS
```

```
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The result would cause an overflow.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
.sp
The \fBcosh()\fR function sets \fBerrno\fR to \fBERANGE\fR if the result would
cause an overflow.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBcosh()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBcoshf()\fR
and \fBcoshl()\fR functions do not set \fBerrno\fR.

.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the complex power function \fIx\fR^\fIy\fR, with a
branch cut for the first parameter along the negative real axis.
.SH RETURN VALUES
.sp
.LP
These functions return the complex power function value.
.SH ERRORS
.sp
.LP
No errors are defined.

\fBlong double complex\fR \fBcprojl\fR(\fBlong double complex\fR \fIz\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute a projection of \fIz\fR onto the Riemann sphere:
\fIz\fR projects to \fIz\fR, except that all complex infinities (even those
with one infinite part and one NaN part) project to positive infinity on the
real axis. If \fIz\fR has an infinite part, then \fBcproj\fR(\fIz\fR) is
equivalent to:
.sp
.in +2
.nf
INFINITY + I * copysign(0.0, cimag(z))
.fi
.in -2

.SH RETURN VALUES
.sp
.LP
These functions return the value of the projection onto the Riemann sphere.
.SH ERRORS
.sp
.LP
No errors are defined.

.fi

.SH DESCRIPTION
.sp
.LP
These function compute the complementary error function 1.0 \(mi
\fBerf(\fR\fIx\fR\fB).\fR
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the value of the
complementary error function.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0, +1 is returned.
.sp
.LP
If \fIx\fR is \(miInf, +2 is returned.
.sp
.LP
If \fIx\fR is +Inf, 0 is returned.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH USAGE
.sp
.LP
```

```
The \fBerfc()\fR function is provided because of the extreme loss of relative
accuracy if \fBerf(\fR\fIx\fR\fB)\fR is called for large \fIx\fR and the result
subtracted from 1.0.

.SH NAME
exp, expf, expl \- exponential function
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBexp\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBfloat\fR \fBexpf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBlong double\fR \fBexpl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the base-\fIe\fR exponential of \fIx\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the exponential value of
\fIx\fR.
.sp
.LP
If the correct value would cause overflow, a range error occurs and
\fBexp()\fR, \fBexpf()\fR, and \fBexpl()\fR return \fBHUGE_VAL\fR,
\fBHUGE_VALF\fR, and \fBHUGE_VALL\fR, respectively.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0, 1 is returned.
.sp
.LP
If \fIx\fR is +Inf, \fIx\fR is returned.
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBexp()\fR as specified by SVID3 and XPG3. See \fBstandards\fR(5).
.SH ERRORS
```

```
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
.sp
The \fBexp()\fR function sets \fBerrno\fR to \fBERANGE\fR if the result
overflows.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBexp()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBexpf()\fR and
\fBexpl()\fR functions do not set \fBerrno\fR.

.mk
.na
```

```
\fBRange Error\fR
.ad
.RS 15n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
The value of \fBexpm1(\fR\fIx\fR\fB)\fR can be more accurate than
\fBexp(\fIx\fR)\fR\(mi1.0 for small values of \fIx\fR.
.sp
.LP
The \fBexpm1()\fR and \fBlog1p\fR(3M) functions are useful for financial
calculations of ((1+\fIx\fR)^\fIn\fR\(mi1)/\fIx\fR, namely:
.sp
.in +2
.nf
\fBexpm1(\fIn\fR * log1p(\fIx\fR))\|/\|\fR\fIx\fR
.fi
.in -2

.sp
.LP
when \fIx\fR is very small (for example, when performing calculations with a
small daily interest rate).  These functions also simplify writing accurate
inverse hyperbolic functions.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <fenv.h>

\fBint\fR \fBfegetenv\fR(\fBfenv_t *\fR\fIenvp\fR);
.fi

.LP
.nf
\fBint\fR \fBfesetenv\fR(\fBconst fenv_t *\fR\fIenvp\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The \fBfegetenv()\fR function attempts to store the current floating-point
environment in the object pointed to by \fIenvp\fR.
.sp
.LP
The \fBfesetenv()\fR function attempts to establish the floating-point
environment represented by the object pointed to by \fIenvp\fR. The \fIenvp\fR
argument points to an object set by a call to \fBfegetenv()\fR or
\fBfeholdexcept\fR(3M), or equals a floating-point environment macro. The
\fBfesetenv()\fR function does not raise floating-point exceptions, but only
installs the state of the floating-point status flags represented through its
argument.
.SH RETURN VALUES
.sp
.LP
If the representation was successfully stored, fegetenv returns 0. Otherwise,
it returns a non-zero value.
.sp
.LP
If the environment was successfully established, fesetenv returns 0. Otherwise,
it returns a non-zero value.
.SH ERRORS
.sp
.LP

.LP
\fBfeholdexcept\fR(3M), \fBfenv.h\fR(3HEAD), \fBfeupdateenv\fR(3M),
\fBattributes\fR(5), \fBstandards\fR(5)
.SH NOTES
.sp
.LP
In a multithreaded program, the \fBfegetenv()\fR and \fBfegetenv()\fR functions
affect the floating point environment only for the calling thread.
.sp
.LP
These functions automatically install and deinstall \fBSIGFPE\fR handlers and
set and clear the trap enable mode bits in the floating point status register
as needed. If a program uses these functions and attempts to install a
\fBSIGFPE\fR handler or control the trap enable mode bits independently, the
resulting behavior is not defined.
.sp
.LP
As described in \fBfex_set_handling\fR(3M)\fB\fR, when a handling function
installed in \fBFEX_CUSTOM\fR mode is invoked, all exception traps are disabled
(and will not be reenabled while \fBSIGFPE\fR is blocked). Thus, attempting to
change the environment from within a handler by calling \fBfesetenv\fR or
\fBfeupdateenv\fR(3M) might not produce the expected results.
```

```

.SH NAME
fegetexceptflag, fesetexceptflag \- get and set floating-point status flags
.SH SYNOPSIS
.LP
.nf
cc [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <fenv.h>

\fBint\fR \fBfegetexceptflag\fR(\fBfexcept_t *\fR\fIflagp\fR, \fBint\fR \fIexcep
.fi

.LP
.nf
\fBint\fR \fBfesetexceptflag\fR(\fBconst fexcept_t *\fR\fIflagp\fR, \fBint\fR \f
.fi

.SH DESCRIPTION
.sp
.LP
The \fBfegetexceptflag()\fR function attempts to store an
implementation-defined representation of the states of the floating-point
status flags indicated by the \fIexcepts\fR argument in the object pointed to
by the \fIflagp\fR argument.
.sp
.LP
The \fBfesetexceptflag()\fR function attempts to set the floating-point status
flags indicated by the \fIexcepts\fR argument to the states stored in the
object pointed to by \fIflagp\fR. The value pointed to by \fIflagp\fR will have
been set by a previous call to \fBfegetexceptflag()\fR whose second argument
represented at least those floating-point exceptions represented by the
\fIexcepts\fR argument. This function does not raise floating-point exceptions
but only sets the state of the flags.
.SH RETURN VALUES
.sp
.LP
If the representation was successfully stored, \fBfegetexceptflag()\fR returns
0. Otherwise, it returns a non-zero value.
.sp
.LP
If the excepts argument is 0 or if all the specified exceptions were
successfully set, \fBfesetexceptflag()\fR returns 0. Otherwise, it returns a
non-zero value.
.SH ERRORS
.sp
.LP
No errors are defined.

.SH NAME
fegetround, fesetround \- get and set current rounding direction
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <fenv.h>

\fBint\fR \fBfegetround\fR(\fBvoid\fR);
.fi

.LP
.nf
\fBint\fR \fBfesetround\fR(\fBint\fR \fIround\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The fegetround function gets the current rounding direction.
.sp
.LP
The fesetround function establishes the rounding direction represented by its
argument round. If the argument is not equal to the value of a rounding
direction macro, the rounding direction is not changed.
.SH RETURN VALUES
.sp
.LP
The fegetround function returns the value of the rounding direction macro
representing the current rounding direction, or a negative value if there is no
such rounding direction macro or the current rounding direction is not
determinable.
.sp
.LP
The fesetround function returns a 0 value if and only if the requested rounding
direction was established.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH EXAMPLES
.sp
.LP
The following example saves, sets, and restores the rounding direction,
reporting an error and aborting if setting the rounding direction fails:
.LP
\fBExample 1 \fRSave, set, and restore the rounding direction.
.sp
.in +2
.nf
```

```
#include <fenv.h>

.SH NAME
feraiseexcept \- raise floating-point exception
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <fenv.h>

\fBint\fR \fBferaiseexcept\fR(\fBint\fR \fIexcepts\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The \fBferaiseexcept()\fR function attempts to raise the supported
floating-point exceptions represented by the \fIexcepts\fR argument. The order
in which these floating-point exceptions are raised is unspecified.
.SH RETURN VALUES
.sp
.LP
If \fIexcepts\fR is 0 or if all the specified exceptions were successfully
raised, \fBferaiseexcept()\fR returns 0. Otherwise, it returns a non-zero
value.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH USAGE
.sp
.LP
The effect is intended to be similar to that of floating-point exceptions
raised by arithmetic operations. Hence, enabled traps for floating-point
exceptions raised by this function are taken.
.SH ATTRIBUTES

.SH NAME
fesetprec, fegetprec \- control floating point rounding precision modes
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... -lm [ \fIlibrary\fR... ]
#include <fenv.h>

\fBint\fR \fBfesetprec\fR(\fBint\fR \fIprec\fR);
.fi

.LP
.nf
\fBint\fR \fBfegetprec\fR(\fBvoid\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The IEEE 754 standard defines rounding precision modes for systems that always
deliver intermediate results to destinations in extended double precision
format. These modes allow such systems to deliver correctly rounded single and
double precision results (in the absence of underflow and overflow) with only
one rounding.
.sp
.LP
The \fBfesetprec()\fR function sets the current rounding precision to the
precision specified by \fIprec\fR, which must be one of the following values
defined in <\fBfenv.h\fR>:
.sp
.ne 2
.mk
.na
\fB\fBFE_FLTPREC\fR\fR
.ad
.RS 15n
.rt
round to single precision
.RE

.sp
.ne 2
.mk
.na
\fB\fBFE_DBLPREC\fR\fR
.ad
.RS 15n
.rt
round to double precision
.RE

.sp
.ne 2
.mk
.na
```

```
\fB\fBFE_LDBLPREC\fR\fR
.ad
.RS 15n
.rt
round to extended double precision
.RE

.sp
.LP
The default rounding precision when a program starts is \fBFE_LDBLPREC\fR.
.sp
.LP
The \fBfegetprec()\fR function returns the current rounding precision.
.SH RETURN VALUES
.sp
.LP
The \fBfesetprec()\fR function returns a non-zero value if the requested
rounding precision is established and 0 otherwise.
.SH ATTRIBUTES
.sp

.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <fenv.h>

\fBint\fR \fBfeupdateenv\fR(\fBconst fenv_t *\fR\fIenvp\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The \fBfeupdateenv()\fR function attempts to save the currently raised
floating-point exceptions in its automatic storage, attempts to install the
floating-point environment represented by the object pointed to by \fIenvp\fR,
and then attempts to raise the saved floating-point exceptions. The \fIenvp\fR
argument points to an object set by a call to \fBfegetenv\fR(3M) or
\fBfeholdexcept\fR(3M), or equals a floating-point environment macro.
.SH RETURN VALUES
.sp
.LP
The \fBfeupdateenv()\fR function returns 0 if and only if all the required
actions were successfully carried out.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH EXAMPLES
.sp
.LP
The following example demonstrates sample code to hide spurious underflow
floating-point exceptions:
.LP
\fBExample 1 \fRHide spurious underflow floating-point exceptions.
.sp

\fBattributes\fR(5), \fBstandards\fR(5)
.SH NOTES
.sp
.LP
In a multithreaded program, the \fBfeupdateenv()\fR function affects the
floating point environment only for the calling thread.
.sp
.LP
When the \fBFEX_CUSTOM\fR handling mode is in effect for an exception, raising
that exception using \fBfeupdateenv()\fR causes the handling function to be
invoked. The handling function can then modify the exception flags to be set as
described in \fBfex_set_handling\fR(3M).  Any result value the handler supplies
will be ignored.
.sp
.LP
The \fBfeupdateenv()\fR function automatically installs and deinstalls
\fBSIGFPE\fR handlers and sets and clears the trap enable mode bits in the
floating point status register as needed. If a program uses these functions and
attempts to install a \fBSIGFPE\fR handler or control the trap enable mode bits
independently, the resulting behavior is not defined.
.sp
.LP
As described in \fBfex_set_handling\fR(3M), when a handling function installed
in \fBFEX_CUSTOM\fR mode is invoked, all exception traps are disabled (and will
not be reenabled while \fBSIGFPE\fR is blocked). Thus, attempting to change the
environment from within a handler by calling \fBfesetenv\fR(3M) or
\fBfeupdateenv\fR might not produce the expected results.
```

```

.SH DESCRIPTION
.sp
.LP
These functions provide control of floating point exception handling modes. For
each function, the \fIex\fR argument specifies one or more exceptions indicated
by a bitwise-OR of any of the following values defined in <\fBfenv.h\fR>:
.sp
.ne 2

all exceptions
.RE

.sp
.LP
The \fBfex_set_handling()\fR function establishes the specified \fImode\fR for
handling the floating point exceptions identified by \fIex\fR.  The selected
\fImode\fR determines the action to be taken when one of the indicated
exceptions occurs.  It must be one of the following values:
.sp
.ne 2
.mk
.na
\fB\fBFEX_NOHANDLER\fR\fR
.ad
.RS 17n
.rt
Trap but do not otherwise handle the exception, evoking instead whatever
ambient behavior would normally be in effect.  This is the default behavior
when the exception's trap is enabled. The \fIhandler\fR parameter is ignored.
.RE

.sp
.ne 2

.mk
.na
\fB\fBFEX_SIGNAL\fR\fR
.ad
.RS 17n
.rt
Invoke the function *\fIhandler\fR with the parameters normally supplied to a
signal handler installed with \fBsigfpe\fR(3C).
.RE

.sp
.ne 2
.mk
.na
\fB\fBFEX_CUSTOM\fR\fR
.ad
.RS 17n
.rt
Invoke the function *\fIhandler\fR as described in the next paragraph.
.RE

.sp
.LP
In \fBFEX_CUSTOM\fR mode, when a floating point exception occurs, the handler
function is invoked as though its prototype were:
.sp
.in +2
.nf
#include <fenv.h>
void handler(int ex, fex_info_t *info);
.fi
.in -2

.sp
.LP
On entry, \fIex\fR is the value (of the first twelve listed above)
corresponding to the exception that occurred, \fBinfo->op\fR indicates the
operation that caused the exception, \fBinfo->op1\fR and \fBinfo->op2\fR
contain the values of the operands, \fBinfo->res\fR contains the default
untrapped result value, and \fBinfo->flags\fR reflects the exception flags that
the operation would have set had it not been trapped.  If the handler returns,
the value contained in \fBinfo->res\fR on exit is substituted for the result of
the operation, the flags indicated by \fBinfo->flags\fR are set, and execution
resumes at the point where the exception occurred.  The handler might modify
\fBinfo->res\fR and \fBinfo->flags\fR to supply any desired result value and
flags.  Alternatively, if the exception is underflow or overflow, the hander
might set
.sp
.LP
info->res.type = fex_nodata;
.sp
.LP
which causes the exponent-adjusted result specified by IEEE 754 to be
substituted.  If the handler does not modify \fBinfo->res\fR or
\fBinfo->flags\fR, the effect is the same as if the exception had not been
trapped.
.sp
.LP
Although the default untrapped result of an exceptional operation is always
available to a \fBFEX_CUSTOM\fR handler, in some cases, one or both operands
may not be.  In these cases, the handler may be invoked with \fBinfo->op1.type
```

```
== fex_nodata\fR or \fBinfo->op2.type == fex_nodata\fR to indicate that the
respective data structures do not contain valid data.  (For example,
\fBinfo->op2.type == fex_nodata\fR if the exceptional operation is a unary
operation.)  Before accessing the operand values, a custom handler should
always examine the \fBtype\fR field of the operand data structures to ensure
that they contain valid data in the appropriate format.
.sp
.LP
The \fBfex_get_handling()\fR function returns the current handling mode for the
exception specified by \fIex\fR, which must be one of the first twelve
exceptions listed above.
.sp
.LP
The \fBfex_getexcepthandler()\fR function saves the current handling modes and
associated data for the exceptions specified by \fIex\fR in the data structure
pointed to by \fIbuf\fR. The type \fBfex_handler_t\fR is defined in
<\fBfenv.h\fR>.
.sp
.LP
The \fBfex_setexcepthandler()\fR function restores the handling modes and
associated data for the exceptions specified by \fIex\fR from the data
structure pointed to by \fIbuf\fR.  This data structure must have been set by a
previous call to \fBfex_getexcepthandler()\fR. Otherwise the effect on the
indicated modes is undefined.
.SH RETURN VALUES
.sp
.LP
The \fBfex_set_handling()\fR function returns a non-zero value if the requested
exception handling mode is established. Otherwise, it returns 0.
.SH EXAMPLES
.sp
.LP
The following example demonstrates how to substitute a predetermined value for
the result of a 0/0 invalid operation.
.sp
.in +2
.nf
#include <math.h>
#include <fenv.h>

double k;

void presub(int ex, fex_info_t *info) {
        info->res.type = fex_double;
        info->res.val.d = k;
}

int main() {
        double x, w;
        int i;
        fex_handler_t buf;
/*
 * save current 0/0 handler
 */
        (void) fex_getexcepthandler(&buf, FEX_INV_ZDZ);
/*
 * set up presubstitution handler for 0/0
 */
        (void) fex_set_handling(FEX_INV_ZDZ, FEX_CUSTOM, presub);
/*
 *  compute (k*x)/sin(x) for k=2.0, x=0.5, 0.4, ..., 0.1, 0.0
 */
        k = 2.0;
        (void) printf("Evaluating f(x) = (k*x)/sin(x)\en\en");
        for (i = 5; i >= 0; i--) {
                x = (double) i * 0.1;
```

```
392                 w = (k * x) / sin(x);
393                 (void) printf("\etx=%3.3f\et f(x) = % 1.20e\en", x, w);
394         }
395 /*
396  * restore old 0/0 handler
397  */
398         (void) fex_setexcepthandler(&buf, FEX_INV_ZDZ);
399         return 0;
400 }
401 .fi
402 .in -2

404 .sp
405 .LP
406 The output from the preceding program reads:
407 .sp
408 .in +2
409 .nf
410 Evaluating f(x) = (k*x)/sin(x)

412         x=0.500  f(x) =  2.08582964293348816000e+00
413         x=0.400  f(x) =  2.05434596443822626000e+00
414         x=0.300  f(x) =  2.03031801709447368000e+00
415         x=0.200  f(x) =  2.01339581906893761000e+00
416         x=0.100  f(x) =  2.00333722632695554000e+00
417         x=0.000  f(x) =  2.00000000000000000000e+00
418 .fi
419 .in -2

421 .sp
422 .LP
423 When \fIx\fR = 0, \fIf(x)\fR is computed as 0/0 and an invalid operation
424 exception occurs.  In this example, the value 2.0 is substituted for the
425 result.

452 .SH NOTES
453 .sp
454 .LP
455 In a multithreaded application, the preceding functions affect exception
456 handling modes only for the calling thread.
457 .sp
```

```
458 .LP
459 The functions described on this page automatically install and deinstall
460 \fBSIGFPE\fR handlers and set and clear the trap enable mode bits in the
461 floating point status register as needed.  If a program uses these functions
462 and attempts to install a \fBSIGFPE\fR handler or control the trap enable mode
463 bits independently, the resulting behavior is not defined.
464 .sp
465 .LP
466 All traps are disabled before a handler installed in \fBFEX_CUSTOM\fR mode is
467 invoked.  When the \fBSIGFPE\fR signal is blocked, as it is when such a handler
468 is invoked, the floating point environment, exception flags, and retrospective
469 diagnostic functions described in \fBfeclearexcept\fR(3M), \fBfegetenv\fR(3M),
470 and \fBfex_set_log\fR(3M) do not re-enable traps.  Thus, the handler itself
471 always runs in \fBFEX_NONSTOP\fR mode with logging of retrospective diagnostics
472 disabled.  Attempting to change these modes within the handler may not produce
473 the expected results.
```

```

.LP
.nf
\fBvoid\fR \fBfex_log_entry\fR(\fBconst char *\fR\fImsg\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The \fBfex_set_log()\fR function enables logging of retrospective diagnostic
messages regarding floating point exceptions to the file specified by \fIfp\fR.
If \fIfp\fR is \fINULL\fR, logging is disabled.  When a program starts, logging
is initially disabled.
.sp
.LP
The occurrence of any of the twelve exceptions listed in
\fBfex_set_handling\fR(3M) constitutes an event that can be logged.  To prevent
the log from becoming exhorbitantly long, the logging mechanism eliminates
redundant entries by two methods.  First, each exception is associated with a
\fIsite\fR in the program.  The site is identified by the address of the
instruction that caused the exception together with a stack trace.  Only the
first exception of a given type to occur at a given site will be logged.
Second, when \fBFEX_NONSTOP\fR handling mode is in effect for some exception,
only those occurrences of that exception that set its previously clear flag are
logged.  Clearing a flag using \fBfeclearexcept()\fR allows the next occurrence
of the exception to be logged provided it does not occur at a site at which it
was previously logged.
.sp
.LP
```

```
Each of the different types of invalid operation exceptions can be logged at
the same site.  Because all invalid operation exceptions share the same flag,
however, of those types for which \fBFEX_NONSTOP\fR mode is in effect, only the
first exception to set the flag will be logged.  When the invalid operation
exception is raised by a call to \fBferaiseexcept\fR(3M) or
\fBfeupdateenv\fR(3M), which type of invalid operation is logged depends on the
implementation.
.sp
.LP
If an exception results in the creation of a log entry, the entry is created at
the time the exception occurs and before any exception handling actions
selected with \fBfex_set_handling()\fR are taken.  In particular, the log entry
is available even if the program terminates as a result of the exception.  The
log entry shows the type of exception, the address of the instruction that
caused it, how it will be handled, and the stack trace. If symbols are
available, the address of the excepting instruction and the addresses in the
stack trace are followed by the names of the corresponding symbols.
.sp
.LP
The \fBfex_get_log()\fR function returns the current log file.
.sp
.LP
The \fBfex_set_log_depth()\fR sets the maximum depth of the stack trace
recorded with each exception to \fIdepth\fR stack frames.  The default depth is
100.
.sp
.LP
The\fBfex_get_log_depth()\fR function returns the current maximum stack trace
depth.
.sp
.LP
The \fBfex_log_entry()\fR function adds a user-supplied entry to the log.  The
entry includes the string pointed to by \fImsg\fR and the stack trace.  Like
entries for floating point exceptions, redundant user-supplied entries are
eliminated: only the first user-supplied entry with a given \fImsg\fR to be
requested from a given site will be logged.  For the purpose of a user-supplied
entry, the site is defined only by the stack trace, which begins with the
function that called \fBfex_log_entry()\fR.
.SH RETURN VALUES
.sp
.LP
The \fBfex_set_log()\fR function returns a non-zero value if logging is enabled
or disabled accordingly and returns 0 otherwise.  The \fBfex_set_log_depth()\fR
returns a non-zero value if the requested stack trace depth is established
(regardless of whether logging is enabled) and returns 0 otherwise.
.SH EXAMPLES
.sp
.LP
The following example demonstrates the output generated when a floating point
overflow occurs in \fBsscanf\fR(3C).
.sp
.in +2
.nf
#include <fenv.h>

int
main() {
        double x;
/*
 * enable logging of retrospective diagnostics
 */
        (void) fex_set_log(stdout);
/*
 * establish default handling for overflows
 */
        (void) fex_set_handling(FEX_OVERFLOW, FEX_NONSTOP, NULL);
```

```
/*
 * trigger an overflow in sscanf
 */
        (void) sscanf("1.0e+400", "%lf", &x);
        return 0;
}
.fi
.in -2

.sp
.LP
The output from the preceding program reads:
.sp
.in +2
.nf
Floating point overflow at 0xef71cac4 __base_conversion_set_exceptio
n, nonstop mode
   0xef71cacc  __base_conversion_set_exception
   0xef721820  _decimal_to_double
   0xef75aba8  number
   0xef75a94c  __doscan_u
   0xef75ecf8  sscanf
   0x00010f20  main
.fi
.in -2

.sp
.LP
Recompiling the program or running it on another system can produce different
text addresses from those shown above.
.SH ATTRIBUTES

.sp
.LP
\fINumerical Computation Guide\fR
.SH NOTES
.sp
.LP
All threads in a process share the same log file.  Each call to
\fBfex_set_log()\fR preempts the previous one.
.sp
.LP
In addition to the log file itself, two additional file descriptors are used
during the creation of a log entry in order to obtain symbol names from the
executable and any shared objects it uses.  These file descriptors are
```

```
relinquished once the log entry is written.  If the file descriptors cannot be
allocated, symbols names are omitted from the stack trace.
.sp
.LP
The functions described on this page automatically install and deinstall
\fBSIGFPE\fR handlers and set and clear the trap enable mode bits in the
floating point status register as needed.  If a program uses these functions
and attempts to install a \fBSIGFPE\fR handler or control the trap enable mode
bits independently, the resulting behavior is not defined.
.sp
.LP
As described in \fBfex_set_handling()\fR, when a handling function installed in
\fBFEX_CUSTOM\fR mode is invoked, all exception traps are disabled (and will
not be reenabled while \fBSIGFPE\fR is blocked).  Thus, retrospective
diagnostic messages are not logged for exceptions that occur within such a
handler.
```

.SH DESCRIPTION
.sp
.LP
These functions compute the largest integral value not greater than \fIx\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the largest integral value
not greater than \fIx\fR, expressed as a \fBdouble\fR, \fBfloat\fR, or \fBlong
double\fR, as appropriate for the return type of the function.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-Inf or \(+-0, \fIx\fR is returned.

.SH NAME
fma, fmaf, fmal \- floating-point multiply-add
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBfma\fR(\fBdouble\fR \fIx\fR, \fBdouble\fR \fIy\fR, \fBdouble\fR
.fi

.LP
.nf
\fBfloat\fR \fBfmaf\fR(\fBfloat\fR \fIx\fR, \fBfloat\fR \fIy\fR, \fBfloat\fR \fI
.fi

.LP
.nf
\fBlong double\fR \fBfmal\fR(\fBlong double\fR \fIx\fR, \fBlong double\fR \fIy\f
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute (\fIx\fR * \fIy\fR) + \fIz\fR, rounded as one ternary
operation. They compute the value (as if) to infinite precision and round once
to the result format, according to the rounding mode characterized by the value
of \fBFLT_ROUNDS\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return (\fIx\fR * \fIy\fR) +
\fIz\fR, rounded as one ternary operation.
.sp
.LP
If \fIx\fR or \fIy\fR are NaN, a NaN is returned.
.sp
.LP
If \fIx\fR multiplied by \fIy\fR is an exact infinity and \fIz\fR is also an
infinity but with the opposite sign, a domain error occurs and a NaN is
returned.
.sp
.LP
If one of \fIx\fR and \fIy\fR is infinite, the other is 0, and \fIz\fR is not a
NaN, a domain error occurs and a NaN is returned.
.sp
.LP
If \fIx\fR*\fIy\fR is not 0*Inf nor Inf*0 and \fIz\fR is a NaN, a NaN is
returned.
.SH ERRORS
.sp
```

```
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The value of \fIx\fR*\fIy\fR+\fIz\fR is invalid or the value \fIx\fR*\fIy\fR is
invalid.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception will be raised.
.RE

.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 16n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception will be raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.fi

.SH DESCRIPTION
.sp
.LP
These functions return the floating-point remainder of the division of \fIx\fR
by \fIy\fR.
.SH RETURN VALUES
.sp
.LP
These functions return the value \fIx\fR \(mi \fIi\fR * \fIy\fR, for some
integer \fIi\fR such that, if \fIy\fR is non-zero, the result has the same sign
as \fIx\fR and magnitude less than the magnitude of \fIy\fR.
.sp
.LP
If \fIx\fR or \fIy\fR is NaN, a NaN is returned.
.sp
.LP
If \fIy\fR is 0, a domain error occurs and a NaN is returned.
.sp
.LP
If \fIx\fR is infinite, a domain error occurs and a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0 and \fIy\fR is not 0, \(+-0 is returned.
.sp
.LP
If \fIx\fR is not infinite and \fIy\fR is \(+-Inf, \fIx\fR is returned.
.SH ERRORS
.sp
```

```
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is infinite or \fIy\fR is 0.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.LP
.nf
\fBlong double\fR \fBhypotl\fR(\fBlong double\fR \fIx\fR, \fBlong double\fR \fIy
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the length of the square root of \fIx\fR^2 + \fIy\fR^2
without undue overflow or underflow.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the length of the hypotenuse
of a right angled triangle with sides of length \fIx\fR^2 and \fIy\fR^2.
.sp
.LP
If the correct value would cause overflow, a range error occurs and
\fBhypot()\fR, \fBhypotf()\fR, and \fBhypotl()\fR return the value of the macro
\fBHUGE_VAL\fR, \fBHUGE_VALF\fR, and \fBHUGE_VALL\fR, respectively.
.sp
.LP
If \fIx\fR or \fIy\fR is \(+-Inf, +Inf is returned even if one of \fIx\fR or
\fIy\fR is NaN.
.sp
.LP
If \fIx\fR or \fIy\fR is NaN and the other is not \(+-Inf, a NaN is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
```

```
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
\fBhypot\fR(\fIx\fR,\fIy\fR), \fBhypot\fR(\fIy\fR,\fIx\fR), and
\fBhypot\fR(\fIx\fR, \(mi\fIy\fR) are equivalent.
.sp
.LP
\fBhypot\fR(\fIx\fR, \(+-0) is equivalent to \fBfabs\fR(\fIx\fR).
.sp
.LP
These functions takes precautions against underflow and overflow during
intermediate steps of the computation.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.SH NAME
ilogb, ilogbf, ilogbl \- return an unbiased exponent
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBint\fR \fBilogb\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBint\fR \fBilogbf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBint\fR \fBilogbl\fR(\fBlong double\fR \fIx\fR);
.fi

.LP
.nf
cc [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBint\fR \fBilogb\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBint\fR \fBilogbf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBint\fR \fBilogbl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions return the exponent part of their argument \fIx\fR.  Formally,
the return value is the integral part of  \fBlog\fR(r)| \fIx\fR | as a signed
integral value, for non-zero \fIx\fR, where \fIr\fR is the radix of the
machine's floating point arithmetic, which is the value of \fBFLT_RADIX\fR
defined in <\fBfloat.h\fR>.
.SH RETURN VALUES
.sp
```

```
.LP
Upon successful completion, these functions return the exponent part of \fIx\fR
as a signed integer value. They are equivalent to calling the corresponding
\fBlogb\fR(3M) function and casting the returned value to type \fBint\fR.
.sp
.LP
If \fIx\fR is 0, the value \fBFP_ILOGB0\fR is returned. For SUSv3-conforming
applications compiled with the \fBc99\fR compiler driver (see
\fBstandards\fR(5)), a domain error occurs.
.sp
.LP
If \fIx\fR is \(+-Inf, the value \fBINT_MAX\fR is returned. For
SUSv3-conforming applications compiled with the \fBc99\fR compiler driver, a
domain error occurs.
.sp
.LP
If \fIx\fR is NaN, the value \fBFP_ILOGBNAN\fR is returned. For
SUSv3-conforming applications compiled with the \fBc99\fR compiler driver, a
domain error occurs.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is zero, NaN, or \(+-Inf.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, then the invalid floating-point exception is raised.

.fi

.SH DESCRIPTION
.sp
.LP
The \fBisgreater()\fR macro determines whether its first argument is greater
than its second argument. The value of \fBisgreater\fR(\fIx\fR, \fIy\fR) is
equal to (\fIx\fR) > (\fIy\fR); however, unlike (\fIx\fR) > (\fIy\fR),
\fBisgreater\fR(\fIx\fR, \fIy\fR) does not raise the invalid floating-point
exception when \fIx\fR and \fIy\fR are unordered.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, the \fBisgreater()\fR macro returns the value of
(\fIx\fR) > (\fIy\fR).
.sp
.LP
If x or y is NaN, 0 is returned.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH USAGE
.sp
.LP
The relational and equality operators support the usual mathematical
relationships between numeric values. For any ordered pair of numeric values,
exactly one of the relationships (less, greater, and equal) is true. Relational
operators can raise the invalid floating-point exception when argument values
are NaNs. For a NaN and a numeric value, or for two NaNs, just the unordered
relationship is true. This macro is a quiet (non-floating-point exception
raising) version of a relational operator. It facilitates writing efficient
code that accounts for quiet NaNs without suffering the invalid floating-point
exception. In the \fBSYNOPSIS\fR section, \fBreal-floating\fR indicates that
the argument is an expression of \fBreal-floating\fR type.

#include <math.h>

\fBint\fR \fBisnan\fR(\fBreal\(emfloating\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
In C90 mode, the \fBisnan()\fR function tests whether \fIx\fR is NaN.
.sp
.LP
In C99 mode, the \fBisnan()\fR macro determines whether its argument value is
NaN. First, an argument represented in a format wider than its semantic type is
converted to its semantic type. The determination is then based on the type of
the argument.
.SH RETURN VALUES
.sp
.LP
Both the \fBisnan()\fR function and macro return non-zero if and only if
\fIx\fR is NaN.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH WARNINGS
.sp
.LP
In C99 mode, the practice of explicitly supplying a prototype for \fBisnan()\fR
after the line
.sp

isnormal \- test for a normal value
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBint\fR \fBisnormal\fR(\fBreal-floating\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The \fBisnormal()\fR macro determines whether its argument value is normal
(neither zero, subnormal, infinite, nor NaN). First, an argument represented in
a format wider than its semantic type is converted to its semantic type. Then
determination is based on the type of the argument.
.SH RETURN VALUES
.sp
.LP
The \fBisnormal()\fR macro returns a non-zero value if and only if its argument
has a normal value.
.SH ERRORS
.sp
.LP
No errors are defined.

.TH isunordered 3M "12 Jul 2006" "SunOS 5.11" "Mathematical Library Functions"
.SH NAME
isunordered \- test if arguments are unordered
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBint\fR \fBisunordered\fR(\fBreal-floating\fR \fIx\fR, \fBreal-floating\fR \fI
.fi

.SH DESCRIPTION
.sp
.LP
The \fBisunordered()\fR macro determines whether its arguments are unordered.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, the \fBisunordered()\fR macro returns 1 if its
arguments are unordered and 0 otherwise.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH USAGE
.sp
.LP
The relational and equality operators support the usual mathematical
relationships between numeric values. For any ordered pair of numeric values,
exactly one of the relationships (less, greater, and equal) is true. Relational
operators can raise the invalid floating-point exception when argument values
are NaNs. For a NaN and a numeric value, or for two NaNs, just the unordered
relationship is true. This macro is a quiet (non-floating-point exception
raising) version of a relational operator. It facilitates writing efficient
code that accounts for quiet NaNs without suffering the invalid floating-point
exception. In the \fBSYNOPSIS\fR section, \fBreal-floating\fR indicates that
the argument shall be an expression of \fBreal-floating\fR type.

.TH ldexp 3M "12 Jul 2006" "SunOS 5.11" "Mathematical Library Functions"
.SH NAME
ldexp, ldexpf, ldexpl \- load exponent of a floating point number
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBldexp\fR(\fBdouble\fR x, \fBint\fR exp);
.fi

.LP
.nf
\fBfloat\fR \fBldexpf\fR(\fBfloat\fR x, \fBint\fR exp);
.fi

.LP
.nf
\fBlong double\fR \fBldexpl\fR(\fBlong double\fR x, \fBint\fR exp);
.fi

.SH DESCRIPTION
.sp
.LP
These functions computes the quantity x\|* 2^exp.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return \fIx\fR multiplied by 2
raised to the power \fIexp\fR.
.sp
.LP
If these functions would cause overflow, a range error occurs and
\fBldexp()\fR, \fBldexpf()\fR, and \fBldexpl()\fR return \fB\(+-HUGE_VAL\fR,
\fB\(+-HUGE_VALF\fR, and \fB\(+-HUGE_VALL\fR (according to the sign of
\fIx\fR), respectively.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0 or \(+-Inf, \fIx\fR is returned.
.sp
.LP
If \fIexp\fR  is 0, \fIx\fR is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
```

```
.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
.sp
The \fBldexp()\fR function sets \fBerrno\fR to \fBERANGE\fR if the result
overflows.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBldexp()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBldexpf()\fR
and \fBldexpl()\fR functions do not set \fBerrno\fR.
.SH ATTRIBUTES

.fi

.SH DESCRIPTION
.sp
.LP
These functions return
.sp
ln||~(x)|
.sp
.LP
where
.sp
|~(x) = integral from 0 to +Infinity of pow(t,x-1)*exp(-t) dt
.sp
.LP
for x > 0 and
.sp
|~(x) = n/(|~(1-x)sin(nx))
.sp
.LP
for x < 1.
.sp
.LP
These functions use the external integer \fBsigngam\fR to return the sign of
\fB|~(x)\fR while \fBlgamma_r()\fR and \fBgamma_r()\fR use the user-allocated
space addressed by \fBsigngamp\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the logarithmic gamma of
\fIx\fR.
.sp
.LP
If \fIx\fR is a non-positive integer, a pole error occurs and these functions
return +\fBHUGE_VAL\fR, +\fBHUGE_VALF\fR, and +\fBHUGE_VALL\fR, respectively.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is 1 or 2, +0 shall be returned.
.sp
.LP
If \fIx\fR is \(+-Inf, +Inf is returned.
.SH ERRORS
```

```
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBPole Error\fR
.ad
.RS 14n
.rt
The \fIx\fR argument is a negative integer or 0.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, then the divide-by-zero floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
In the case of \fBlgamma()\fR, do not use the expression
\fBsigngam*exp(lgamma(x))\fR to compute
.sp
'g  := |~(x)'
.sp
.LP
Instead compute \fBlgamma()\fR first:
.sp
.LP
\fBlg = lgamma(x); g = signgam*exp(lg);\fR
.sp
.LP
only after \fBlgamma()\fR has returned can \fBsigngam\fR be correct. Note that
\fB|~(x)\fR must overflow when \fIx\fR is large enough, underflow when
\(mi\fIx\fR is large enough, and generate a division by 0 exception at the
singularities \fIx\fR a nonpositive integer.

\fBlong long\fR \fBllrintl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions round their argument to the nearest integer value, rounding
according to the current rounding direction.
.SH RETURN VALUES
.sp
.LP
 Upon successful completion, these functions return the rounded integer value.
.sp
.LP
If \fIx\fR is NaN, a domain error occurs and an unspecified value is returned.
.sp
.LP
If \fIx\fR is +Inf, a domain error occurs and an unspecified value is returned.
.sp
.LP
If \fIx\fR is -Inf, a domain error occurs and an unspecified value is returned.
.sp
.LP
If the correct value is positive and too large to represent as a \fBlong
long\fR, a domain error occurs and an unspecified value is returned.
.sp
.LP
 If the correct value is negative and too large to represent as a \fBlong
long\fR, a domain error occurs and an unspecified value is returned.
.SH ERRORS
.sp
```

```
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is NaN or \(+-Inf, or the correct value is not
representable as an integer.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, then the invalid floating-point exception will be raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
These functions provide floating-to-integer conversions. They round according
to the current rounding direction. If the rounded value is outside the range of
the return type, the numeric result is unspecified and the invalid
floating-point exception is raised. When they raise no other floating-point
exception and the result differs from the argument, they raise the inexact
floating-point exception.

.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The \fIx\fR argument is NaN or \(+-Inf, or the correct value is not
representable as an integer.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, then the invalid floating-point exception will be raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
These functions differ from the \fBllrint\fR(3M) functions in that the default
rounding direction for the \fBllround()\fR functions round halfway cases away
from 0 and need not raise the inexact floating-point exception for non-integer
arguments that round to within the range of the return type.

.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the natural logarithm of their argument \fIx\fR,
log(\fIe\fR)(\fIx\fR).
.SH RETURN VALUES
.sp
.LP
Upon successful completion, \fBlog()\fR returns the natural logarithm of
\fIx\fR.
.sp
.LP
If \fIx\fR is \(+-0, a pole error occurs and \fBlog()\fR, \fBlogf()\fR, and
\fBlogl()\fR return \(mi\fBHUGE_VAL\fR, \(mi\fBHUGE_VALF\fR, and
\(mi\fBHUGE_VALL\fR, respectively.
.sp
.LP
For finite values of \fIx\fR that are less than 0, or if \fIx\fR is \(miInf, a
domain error occurs and a NaN is returned.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is 1, +0 is returned.
.sp
.LP
If \fIx\fR is +Inf, \fIx\fR is returned.
```

```
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBlog()\fR as specified by SVID3 and XPG3.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.fi

.LP
.nf
\fBlong double\fR \fBlogbl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the exponent of \fIx\fR, which is the integral part of
log(\fIr\fR) |\fIx\fR|, as a signed floating point value, for non-zero \fIx\fR,
where \fIr\fR is the radix of the machine's floating-point arithmetic, which is
the value of \fBFLT_RADIX\fR defined in the <\fBfloat.h\fR> header.
.SH RETURN VALUES
.sp
.LP
```

```
Upon successful completion, these functions return the exponent of \fIx\fR.
.sp
.LP
If \fIx\fR is subnormal:
.RS +4
.TP
.ie t \(bu
.el o
For SUSv3-conforming applications compiled with the \fBc99\fR compiler driver
(see \fBstandards\fR(5)), the exponent of \fIx\fR as if \fIx\fR were normalized
is returned.
.RE
.RS +4
.TP
.ie t \(bu
.el o
Otherwise, if compiled with the \fBcc\fR compiler driver, \(mi1022, \(mi126,
and \(mi16382 are returned for \fBlogb()\fR, \fBlogbf()\fR, and \fBlogbl()\fR,
respectively.
.RE
.sp
.LP
If \fIx\fR is \(+-0, a pole error occurs and \fBlogb()\fR, \fBlogbf()\fR, and
\fBlogbl()\fR return \(mi\fBHUGE_VAL\fR, \(mi\fBHUGE_VALF\fR, and
\(mi\fBHUGE_VALL\fR, respectively.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-Inf, +Inf is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBPole Error\fR
.ad
.RS 14n
.rt
The value of \fIx\fR is \(+-0.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the divide-by-zero floating-point exception is raised.
.sp
The \fBlogb()\fR function sets \fBerrno\fR to \fBEDOM\fR if the value of
\fIx\fR is 0.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBlogb()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBlogbf()\fR
and \fBlogbl()\fR functions do not set \fBerrno\fR.
```

.TH matherr 3M "23 Sep 1997" "SunOS 5.11" "Mathematical Library Functions"
.SH NAME
matherr \- math library exception-handling function
.SH SYNOPSIS
.LP
.nf
#include <math.h>

\fBint\fR \fBmatherr\fR(\fBstruct exception *\fR\fIexc\fR);
.fi

.SH DESCRIPTION
.sp
.LP
The System V Interface Definition, Third Edition (SVID3) specifies that certain
\fBlibm\fR functions call \fBmatherr()\fR when exceptions are detected. Users
may define their own mechanisms for handling exceptions, by including a
function named \fBmatherr()\fR in their programs. The \fBmatherr()\fR function
is of the form described above. When an exception occurs, a pointer to the
exception structure \fIexc\fR will be passed to the user-supplied
\fBmatherr()\fR function.  This structure, which is defined in the
\fB<math.h>\fR header file, is as follows:
.sp
.in +2
.nf
struct exception {
        int type;
        char *name;
        double arg1, arg2, retval;
};
.fi
.in -2

.sp
.LP
The \fBtype\fR member is an integer describing the type of exception that has
occurred, from the following list of constants (defined in the header file):
.sp
.ne 2
.mk
.na
\fB\fBDOMAIN\fR\fR
.ad
.RS 13n
.rt
argument domain exception
.RE

.sp
.ne 2
.mk
.na
\fB\fBSING\fR\fR
.ad
.RS 13n
.rt
```

```
argument singularity
.RE

.sp
.ne 2
.mk
.na
\fB\fBOVERFLOW\fR\fR
.ad
.RS 13n
.rt
overflow range exception
.RE

.sp
.ne 2
.mk
.na
\fB\fBUNDERFLOW\fR\fR
.ad
.RS 13n
.rt
underflow range exception
.RE

.sp
.ne 2
.mk
.na
\fB\fBTLOSS\fR\fR
.ad
.RS 13n
.rt
total loss of significance
.RE

.sp
.ne 2
.mk
.na
\fB\fBPLOSS\fR\fR
.ad
.RS 13n
.rt
partial loss of significance
.RE

.sp
.LP
Both \fBTLOSS\fR and \fBPLOSS\fR reflect limitations of particular algorithms
for trigonometric functions that suffer abrupt declines in accuracy at definite
boundaries. Since the implementation does not suffer such abrupt declines,
\fBPLOSS\fR is never signaled. \fBTLOSS\fR is signaled for Bessel functions
\fIonly\fR to satisfy SVID3 requirements.
.sp
.LP
The \fBname\fR member points to a string containing the name of the function
that incurred the exception. The \fBarg1\fR and \fBarg2\fR members are the
arguments with which the function was invoked. \fBretval\fR is set to the
default value that will be returned by the function unless the user's
\fBmatherr()\fR sets it to a different value.
.sp
.LP
If the user's \fBmatherr()\fR function returns non-zero, no exception message
will be printed and \fBerrno\fR is not set.
.SH SVID3 STANDARD CONFORMANCE
```

```
.sp
.LP
When an application is built as a SVID3 conforming application (see
\fBstandards\fR(5)), if \fBmatherr()\fR is not supplied by the user, the
default matherr exception-handling mechanisms, summarized in the table below,
are invoked upon exception:
.sp
.ne 2
.mk
.na
\fB\fBDOMAIN\fR\fR
.ad
.RS 13n
.rt
0.0 is usually returned, \fBerrno\fR is set to \fBEDOM\fR and a message is
usually printed on standard error.
.RE

.sp
.ne 2
.mk
.na
\fB\fBSING\fR\fR
.ad
.RS 13n
.rt
The largest finite single-precision number, \fBHUGE\fR of appropriate sign, is
returned, \fBerrno\fR is set to \fBEDOM\fR, and a message is printed on
standard error.
.RE

.sp
.ne 2
.mk
.na
\fB\fBOVERFLOW\fR\fR
.ad
.RS 13n
.rt
The largest finite single-precision number, \fBHUGE\fR of appropriate sign, is
usually returned and \fBerrno\fR is set to \fBERANGE\fR.
.RE

.sp
.ne 2
.mk
.na
\fB\fBUNDERFLOW\fR\fR
.ad
.RS 13n
.rt
0.0 is returned and \fBerrno\fR is set to \fBERANGE\fR.
.RE

.sp
.ne 2
.mk
.na
\fB\fBTLOSS\fR\fR
.ad
.RS 13n
.rt
0.0 is returned, \fBerrno\fR is set to \fBERANGE\fR, and a message is printed
on standard error.
.RE
```

```
.sp
.LP
In general, \fBerrno\fR is not a reliable error indicator because it can be
unexpectedly set by a function in a handler for an asynchronous signal.

.LP
.nf
\fBlong double\fR \fBmodfl\fR(\fBlong double\fR \fIx\fR, \fBlong double *\fR\fIi
.fi

.SH DESCRIPTION
.sp
.LP
These functions break the argument \fIx\fR into integral and fractional parts,
each of which has the same sign as the argument. It stores the integral part as
a \fBdouble\fR for the \fBmodf()\fR function, a float for the \fBmodff()\fR
function, or a long double for the\fBmodfl()\fR function in the object pointed
to by \fIiptr\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the signed fractional part
of \fIx\fR.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned and *\fIiptr\fR is set to NaN.
.sp
.LP
If \fIx\fR is \(+-Inf, \(+-0 is returned and *\fIiptr\fR is set to \(+-Inf.
.SH ERRORS
.sp
.LP
No errors are defined.
.SH USAGE
.sp
.LP
These functions compute the function result and *\fIiptr\fR such that:
.sp
```

```
.in +2
.nf
a = modf(x, &iptr) ;
x == a+*iptr ;
.fi
.in -2

.LP
.nf
\fBlong double\fR \fBnexttowardl\fR(\fBlong double\fR \fIx\fR, \fBlong double\fR
.fi

.SH DESCRIPTION
.sp
.LP
The \fBnextafter()\fR, \fBnextafterf()\fR, and \fBnextafterl()\fR functions
compute the next representable floating-point value following \fIx\fR in the
direction of \fIy\fR. Thus, if \fIy\fR is less than \fIx\fR, \fBnextafter()\fR
returns the largest representable floating-point number less than \fIx\fR. The
\fBnextafter()\fR, \fBnextafterf()\fR, and \fBnextafterl()\fR functions return
\fIy\fR if \fIx\fR equals \fIy\fR.
.sp
.LP
The \fBnexttoward()\fR, \fBnexttowardf()\fR, and \fBnexttowardl()\fR functions
```

```
are equivalent to the corresponding \fBnextafter()\fR functions, except that
the second parameter has type \fBlong double\fR and the functions return
\fIy\fR converted to the type of the function if \fIx\fR equals \fIy\fR.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the next representable
floating-point value following \fIx\fR in the direction of \fIy\fR.
.sp
.LP
If \fIx\fR == \fIy\fR, \fIy\fR (of the type \fIx\fR) is returned.
.sp
.LP
If \fIx\fR is finite and the correct function value would overflow, a range
error occurs and \(+-\fBHUGE_VAL\fR, \(+-\fBHUGE_VALF\fR, and
\(+-\fBHUGE_VALL\fR (with the same sign as \fIx\fR) is returned as appropriate
for the return type of the function.
.sp
.LP
If \fIx\fR or \fIy\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR != \fIy\fR and the correct function value is subnormal, zero, or
underflows, a range error occurs and either the correct function value (if
representable) or 0.0 is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The correct value overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
.sp
The \fBnextafter()\fR function sets \fBerrno\fR to \fBERANGE\fR if the correct
value would overflow.
.RE

.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The correct value underflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the underflow floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
```

```
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBnextafter()\fR.
On return, if \fBerrno\fR is non-zero, an error has occurred. The
\fBnextafterf()\fR, \fBnextafterl()\fR. \fBnexttoward()\fR,
\fBnexttowardf()\fR, and \fBnexttowardl()\fR functions do not set \fBerrno\fR.
.SH ATTRIBUTES
.sp

.SH DESCRIPTION
.sp
.LP
These functions compute the value of \fIx\fR raised to the power \fIy,\fR
\fIx\fR^y>. If \fIx\fR is negative, \fIy\fR must be an integer value.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the value of \fIx\fR raised
to the power \fIy\fR.
```

```
.sp
.LP
For finite values of \fIx\fR < 0, and finite non-integer values of \fIy\fR, a
domain error occurs and either a NaN (if representable), or an
implementation-defined value is returned.
.sp
.LP
If the correct value would cause overflow, a range error occurs and
\fBpow()\fR, \fBpowf()\fR, and \fBpowl()\fR return \fBHUGE_VAL\fR,
\fBHUGE_VALF\fR, and \fBHUGE_VALL\fR, respectively.
.sp
.LP
If \fIx\fR or \fIy\fR is a NaN, a NaN is returned unless:
.RS +4
.TP
.ie t \(bu
.el o
If \fIx\fR is +1 and \fIy\fR is NaN and the application was compiled with the
\fBc99\fR compiler driver and is therefore SUSv3-conforming (see
\fBstandards\fR(5)), 1.0 is returned.
.RE
.RS +4
.TP
.ie t \(bu
.el o
For any value of \fIx\fR (including NaN), if \fIy\fR is +0, 1.0 is returned.
.RE
.sp
.LP
For any odd integer value of \fIy\fR > 0, if \fIx\fR is \(+-0, \(+-0 is
returned.
.sp
.LP
For \fIy\fR > 0 and not an odd integer, if \fIx\fR is \(+-0, +0 is returned.
.sp
.LP
If \fIx\fR is \(+-1 and \fIy\fR is \(+-Inf, and the application was compiled
with the \fBcc\fR compiler driver, NaN is returned. If, however, the
application was compiled with the \fBc99\fR compiler driver and is therefore
SUSv3-conforming (see\fBstandards\fR(5)), 1.0 is returned.
.sp
.LP
For |\fIx\fR| < 1, if \fIy\fR is \(miInf, +Inf is returned.
.sp
.LP
For |\fIx\fR| > 1, if \fIy\fR is \(miInf, +0 is returned.
.sp
.LP
For |\fIx\fR| < 1, if \fIy\fR is +Inf, +0 is returned.
.sp
.LP
For |\fIx\fR| > 1, if \fIy\fR is +Inf, +Inf is returned.
.sp
.LP
For \fIy\fR an odd integer < 0, if \fIx\fR is \(miInf, \(mi0 is returned.
.sp
.LP
For \fIy\fR < 0 and not an odd integer, if \fIx\fR is \(miInf, +0 is returned.
.sp
.LP
For \fIy\fR an odd integer > 0, if \fIx\fR is \(miInf, \(miInf is returned.
.sp
.LP
For \fIy\fR > 0 and not an odd integer, if \fIx\fR is \(miInf, +Inf is
returned.
.sp
```

```
.LP
For \fIy\fR < 0, if \fIx\fR is +Inf, +0 is returned.
.sp
.LP
For \fIy\fR > 0, if \fIx\fR is +Inf, +Inf is returned.
.sp
.LP
For \fIy\fR an odd integer < 0, if \fIx\fR is \(+-0, a pole error occurs and
\(+-\fBHUGE_VAL\fR, \(+-\fBHUGE_VALF\fR, and \(+-\fBHUGE_VALL\fR are returned
for \fBpow()\fR, \fBpowf()\fR, and \fBpowl()\fR, respectively.
.sp
.LP
For \fIy\fR < 0 and not an odd integer, if \fIx\fR is \(+-0, a pole error
occurs and \fBHUGE_VAL\fR, \fBHUGE_VALF\fR, and \fBHUGE_VALL\fR are returned
for \fBpow()\fR, \fBpowf()\fR, and \fBpowl()\fR, respectively.
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBpow()\fR as specified by SVID3 and XPG3.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
.RS 16n
.rt
The value of \fIx\fR is negative and \fIy\fR is a finite non-integer.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.sp
The \fBpow()\fR function sets \fBerrno\fR to \fBEDOM\fR if the value of \fIx\fR
is negative and \fIy\fR is non-integral.
.RE

.sp
.ne 2
.mk
.na
\fBPole Error\fR
.ad
.RS 16n
.rt
The value of \fIx\fR is 0 and \fIy\fR is negative.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the divide-by-zero floating-point exception is raised.
.RE

.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 16n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the overflow floating-point exception is raised.
```

```
.sp
The \fBpow()\fR function sets \fBerrno\fR to \fBEDOM\fR if the value to be
returned would cause overflow.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.
.sp
.LP
An application can also set \fBerrno\fR to 0 before calling \fBpow()\fR. On
return, if \fBerrno\fR is non-zero, an error has occurred. The \fBpowf()\fR and
\fBpowl()\fR functions do not set \fBerrno\fR.

.SH NOTES
.sp
.LP
Prior to Solaris 2.6,  there was a conflict between the \fBpow()\fR function in
this library and the \fBpow()\fR function in the \fBlibmp\fR library. This
conflict was resolved by prepending \fBmp_\fR to all functions in the
\fBlibmp\fR library. See \fBmp\fR(3MP) for more information.

.fi

.SH DESCRIPTION
.sp
.LP
These functions return the floating point remainder \fIr\fR = \fIx\fR \(mi
\fIn\fR\fIy\fR when \fIy\fR is non-zero. The value \fIn\fR is the integral
value nearest the exact value \fIx\fR/\fIy\fR. When |\fIn\fR \(mi
\fIx\fR/\fIy\fR\|| = \(12, the value \fIn\fR is chosen to be even.
.sp
.LP
The behavior of \fBremainder()\fR is independent of the rounding mode.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the floating point remainder
\fIr\fR = \fIx\fR \(mi \fIn\fR\fIy\fR when \fIy\fR is non-zero.
.sp
.LP
If \fIx\fR or \fIy\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is infinite or \fIy\fR is 0 and the other is non-NaN, a domain error
occurs and a NaN is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
```

```
.mk

.fi

.SH DESCRIPTION
.sp
.LP
These functions compute x * \fIr\fR^n, where \fIr\fR is the radix of the
machine's floating point arithmetic. When \fIr\fR is 2, \fBscalb()\fR is
equivalent to \fBldexp\fR(3M). The value of \fIr\fR is \fBFLT_RADIX\fR which is
defined in <\fBfloat.h\fR>.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, the \fBscalb()\fR function returns \fIx\fR *
\fIr\fR^n.
.sp
.LP
If \fIx\fR or \fIn\fR is NaN, a NaN is returned.
.sp
.LP
If \fIn\fR is 0, \fIx\fR is returned.
.sp
.LP
If \fIx\fR is \(+-Inf and \fIn\fR is not \(miInf, \fIx\fR is returned.
.sp
.LP
If \fIx\fR is \(+-0 and \fIn\fR is not +Inf, \fIx\fR is returned.
.sp
.LP
If \fIx\fR is \(+-0 and \fIn\fR is +Inf, a domain error occurs and a NaN is
```

```
returned.
.sp
.LP
If \fIx\fR is \(+-Inf and \fIn\fR is \(miInf, a domain error occurs and a NaN
is returned.
.sp
.LP
If the result would cause an overflow, a range error occurs and
\(+-\fBHUGE_VAL\fR (according to the sign of \fIx\fR) is returned.
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned by
\fBscalb()\fR as specified by SVID3 and XPG3. See \fBstandards\fR(5).
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2

.SH DESCRIPTION
.sp
.LP
These functions compute \fIx\fR * \fBFLT_RADIX\fR^n efficiently, not normally
by computing \fBFLT_RADIX\fR^n explicitly.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return \fIx\fR *
\fBFLT_RADIX\fR^\fIn\fR>.
.sp
.LP
If the result would cause overflow, a range error occurs and these functions
```

```
return \(+-\fBHUGE_VAL\fR, \(+-\fBHUGE_VALF\fR, and \(+-\fBHUGE_VALL\fR
(according to the sign of \fIx\fR) as appropriate for the return type of the
function.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0 or \(+-Inf, \fIx\fR is returned.
.sp
.LP
If \fIx\fR is 0, \fIx\fR is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBRange Error\fR
.ad
.RS 15n
.rt
The result overflows.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, then the overflow floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.SH NAME
tan, tanf, tanl \- tangent function
.SH SYNOPSIS
.LP
.nf
c99 [ \fIflag\fR... ] \fIfile\fR... \fB-lm\fR [ \fIlibrary\fR... ]
#include <math.h>

\fBdouble\fR \fBtan\fR(\fBdouble\fR \fIx\fR);
.fi

.LP
.nf
\fBfloat\fR \fBtanf\fR(\fBfloat\fR \fIx\fR);
.fi

.LP
.nf
\fBlong double\fR \fBtanl\fR(\fBlong double\fR \fIx\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions compute the tangent of their argument \fIx\fR, measured in
radians.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the tangent of \fIx\fR.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is \(+-0, \fIx\fR is returned.
.sp
.LP
If \fIx\fR is \(+-Inf, a domain error occurs and a NaN is returned.
.SH ERRORS
.sp
.LP
These functions will fail if:
.sp
.ne 2
.mk
.na
\fBDomain Error\fR
.ad
```

```
.RS 16n
.rt
The value of \fIx\fR is \(+-Inf.
.sp
If the integer expression (\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is
non-zero, the invalid floating-point exception is raised.
.RE

.SH USAGE
.sp
.LP
There are no known floating-point representations such that for a normal
argument, \fBtan\fR(\fIx\fR) is either overflow or underflow.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

.SH DESCRIPTION
.sp
.LP
These functions compute Bessel functions of \fIx\fR of the second kind of
orders 0, 1 and \fIn\fR, respectively.
.SH RETURN VALUES
.sp
.LP
Upon successful completion, these functions return the relevant Bessel value of
\fIx\fR of the second kind.
.sp
.LP
If \fIx\fR is NaN, a NaN is returned.
.sp
.LP
If \fIx\fR is negative, \(mi\fBHUGE_VAL\fR or NaN is returned.
.sp
.LP
If \fIx\fR is 0.0, \(mi\fBHUGE_VAL\fR is returned.
.sp
.LP
If the correct result would cause overflow, \(mi\fBHUGE_VAL\fR is returned.
.sp
.LP
For exceptional cases, \fBmatherr\fR(3M) tabulates the values to be returned as
specified by SVID3 and XPG3.
.SH ERRORS
.sp
.LP
No errors are returned.
.SH USAGE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. An application should either examine the return value or check the
floating point exception flags to detect exceptions.

     \fBint *\fR\fIstridez\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBatan2\fR(\fIy\fR, \fIx\fR) for an
entire vector of values at once. The first parameter specifies the number of
values to compute. Subsequent parameters specify the argument and result
vectors. Each vector is described by a pointer to the first element and a
stride, which is the increment between successive elements.
.sp
.LP
Specifically, \fBvatan2_\fR(\fIn,\fR \fIy\fR, \fIsy\fR, \fIx\fR, \fIsx\fR,
\fIz\fR, \fIsz\fR) computes \fIz\fR[\fIi\fR * *\fIsz\fR] =
\fBatan2\fR(\fIy\fR[\fIi\fR * *\fIsy\fR], \fIx\fR[\fIi\fR * *\fIsx\fR]) for
each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvatan2f_()\fR  function performs
the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBatan2\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
```

```
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
These functions handle special cases and exceptions in the same way as the
\fBatan2()\fR functions when \fBc99\fR \fBMATHERREXCEPT\fR conventions are in
effect. See \fBatan2\fR(3M) for the results for special cases.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

vatan_, vatanf_ \- vector arctangent functions
.SH SYNOPSIS
.LP
.nf
cc [ \fIflag\fR\&.\|.\|. ] \fIfile\fR\&.\|.\|. \fB-lmvec\fR [ \fIlibrary\fR\&.\|

\fBvoid\fR \fBvatan_\fR(\fBint *\fR\fIn\fR,\fBdouble * restrict\fR \fIx\fR, \fBi
     \fBdouble * restrict\fR \fIy\fR, \fBint *\fR\fIstridey\fR);
.fi

.LP
.nf
\fBvoid\fR \fBvatanf_\fR(\fBint *\fR\fIn\fR, \fBfloat * restrict\fR \fIx\fR, \fB
     \fBfloat * restrict\fR \fIy\fR, \fBint *\fR\fIstridey\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBatan\fR(\fIx\fR) for an entire vector
of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements.
.sp
.LP
Specifically, \fBvatan_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR)
computes \fIy\fR[\fIi\fR * *\fIsy\fR] = \fBatan\fR(\fIx\fR[\fIi\fR *
*\fIsx\fR]) for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvatanf_()\fR
function performs the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBatan\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
```

```
.sp
.LP
These functions handle special cases and exceptions in the same way as the
\fBatan()\fR functions when \fBc99\fR \fBMATHERREXCEPT\fR conventions are in
effect. See \fBatan\fR(3M) for the results for special cases.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBcospi\fR(\fIx\fR), defined by
\fBcospi\fR(\fIx\fR) =  \fBcos\fR(\c
.if n pi\c
.if t \(*p
\c
 * \fIx\fR), for an entire vector of values at once. The first parameter
specifies the number of values to compute. Subsequent parameters specify the
argument and result vectors. Each vector is described by a pointer to the first
element and a stride, which is the increment between successive elements.
.sp
.LP
Specifically, \fBvcospi_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR)
computes \fIy\fR[\fIi\fR * *\fIsy\fR] = \fBcospi\fR(\fIx\fR[\fIi\fR *
*\fIsx\fR]) for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvcospif_()\fR
function performs the same computation for single precision data.
.sp
.LP
Non-exceptional results are accurate to within a unit in the last place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
```

```
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
These functions handle special cases and exceptions in the spirit of IEEE 754.
In particular,
.RS +4
.TP
.ie t \(bu
.el o
\fBcospi\fR(NaN) is NaN,
.RE
.RS +4
.TP
.ie t \(bu
.el o
\fBcospi\fR(\(+-Inf) is NaN, and  an  invalid operation exception is raised.
.RE
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBexp\fR(\fIx\fR) for an entire vector
of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements.
.sp
.LP
Specifically, \fBvexp_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR)
computes \fIy\fR[\fIi\fR * *\fIsy\fR] = \fBexp\fR(\fIx\fR[\fIi\fR * *\fIsx\fR])
for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvexpf_()\fR function
performs the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBexp\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
```

```
.sp
.LP
On SPARC, the \fBvexpf_()\fR function delivers +0 rather than a subnormal
result for arguments in the range -103.2789 <= \fIx\fR <= -87.3365. Otherwise,
these functions handle special cases and exceptions in the same way as the
\fBexp()\fR functions when \fBc99\fR \fBMATHERREXCEPT\fR conventions are in
effect. See \fBexp\fR(3M) for the results for special cases.
.sp
.LP
An application wanting to check for exceptions should call

Specifically, \fBvlog_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR)
computes \fIy\fR[\fIi\fR * *\fIsy\fR] = \fBlog\fR(\fIx\fR[\fIi\fR * *\fIsx\fR])
for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvlogf_()\fR function
performs the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBlog\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
```

```
.sp
.LP
These functions handle special cases and exceptions in the same way as the
\fBlog()\fR functions when \fBc99\fR \fBMATHERREXCEPT\fR conventions are in
effect. See \fBlog\fR(3M) for the results for special cases.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

     \fBint *\fR\fIstridez\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBpow\fR(\fIx\fR, \fIy\fR) for an entire
vector of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements.
.sp
.LP
Specifically, \fBvpow_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR,
\fIz\fR, \fIsz\fR) computes \fIz\fR[\fIi\fR * *\fIsz\fR] =
\fBpow\fR(\fIx\fR[\fIi\fR * *\fIsx\fR], \fIy\fR[\fIi\fR * *\fIsy\fR]) for each
\fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvpowf_()\fR function performs the
same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBpow\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
```

```
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
The results of these functions for special cases and exceptions match that of
the \fBpow()\fR functions when the latter are used in a program compiled with
the \fBcc\fR compiler driver (that is, not SUSv3-conforming) and the expression
(\fBmath_errhandling\fR & \fBMATH_ERREXCEPT\fR) is non-zero. These functions do
not set \fBerrno\fR. See \fBpow\fR(3M) for the results for special cases.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBrhypot\fR(\fIx\fR, \fIy\fR), defined
by \fBrhypot\fR(\fIx\fR, \fIy\fR) = 1 / \fBhypot\fR(\fIx\fR, \fIy\fR), for an
entire vector of values at once. The first parameter specifies the number of
values to compute. Subsequent parameters specify the argument and result
vectors. Each vector is described by a pointer to the first element and a
stride, which is the increment between successive elements.
.sp
.LP
Specifically, \fBvrhypot_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR,
\fIz\fR, \fIsz\fR) computes \fIz\fR[\fIi\fR * *\fIsz\fR] =
\fBrhypot\fR(\fIx\fR[\fIi\fR * *\fIsx\fR], \fIy\fR[\fIi\fR * *\fIsy\fR]) for
each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvrhypotf_()\fR  function
performs the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of evaluating 1.0 / \fBhypot\fR(\fIx\fR, \fIy\fR) given the same
arguments. Non-exceptional results, however, are accurate to within a unit in
the last place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs

.SH DESCRIPTION
.sp
.LP
These functions evaluate both \fBsin\fR(\fIx\fR) and \fBcos\fR(\fIx\fR) for an
entire vector of values at once. The first parameter specifies the number of
values to compute. Subsequent parameters specify the argument and result
vectors. Each vector is described by a pointer to the first element and a
stride, which is the increment between successive elements.
.sp
.LP
Specifically, \fBvsincos_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIs\fR, \fIss\fR,
\fIc\fR, \fIsc\fR) simultaneously computes \fIs\fR[\fIi\fR * *\fIss\fR] =
\fBsin\fR(\fIx\fR[\fIi\fR * *\fIsx\fR]) and \fIc\fR[\fIi\fR * *\fIsc\fR] =
\fBcos\fR(\fIx\fR[\fIi\fR * *\fIsx\fR]) for each \fIi\fR = 0, 1, ..., *\fIn\fR
- 1. The  \fBvsincosf_()\fR function performs the same computation for single
precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBsincos\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
```

```
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
These functions handle special cases and exceptions in the same way as the
\fBsin()\fR and \fBcos()\fR functions when \fBc99\fR \fBMATHERREXCEPT\fR
conventions are in effect. See \fBsin\fR(3M) and \fBcos\fR(3M) for the results
for special cases.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

     \fBint *\fR\fIstridec\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate both \fBsinpi\fR(\fIx\fR) and \fBcospi\fR(\fIx\fR),
defined by \fBsinpi\fR(\fIx\fR) = \fBsin\fR(\c
.if n pi\c
.if t \(*p
\c
 * \fIx\fR) and \fBcospi\fR(\fIx\fR) = \fBcos\fR(\c
.if n pi\c
.if t \(*p
\c
 * \fIx\fR), for an entire vector of values at once. The first parameter
specifies the number of values to compute. Subsequent parameters specify the
argument and result vectors. Each vector is described by a pointer to the first
element and a stride, which is the increment between successive elements.
.sp
.LP
Specifically, \fBvsincospi_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIs\fR, \fIss\fR,
\fIc\fR, \fIsc\fR) simultaneously computes \fIs\fR[\fIi\fR * *\fIss\fR] =
\fBsinpi\fR(\fIx\fR[\fIi\fR * *\fIsx\fR]) and \fIc\fR[\fIi\fR * *\fIsc\fR] =
\fBcospi\fR(\fIx\fR[\fIi\fR * *\fIsx\fR]) for each \fIi\fR = 0, 1, ...,
*\fIn\fR - 1. The  \fBvsincosf_()\fR function performs the same computation for
single precision data.
.sp
.LP
Non-exceptional results are accurate to within a unit in the last place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
```

```
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
These functions handle special cases and exceptions in the spirit of IEEE 754.
In particular,
.RS +4
.TP
.ie t \(bu
.el o
\fBsinpi\fR(NaN), \fBcospi\fR(NaN) are NaN,
.RE
.RS +4
.TP

.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the function \fBsqrt\fR(\fIx\fR) for an entire vector
of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements.
.sp
.LP
Specifically, \fBvsqrt_\fR(\fIn\fR, \fIx\fR, \fIsx\fR, \fIy\fR, \fIsy\fR)
computes \fIy\fR[\fIi\fR * *\fIsy\fR] = \fBsqrt\fR(\fIx\fR[\fIi\fR *
*\fIsx\fR]) for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The  \fBvsqrtf_()\fR
function performs the same computation for single precision data.
.sp
.LP
Unlike their scalar counterparts, these functions do not always deliver
correctly rounded results. However, the error in each non-exceptional result is
less than one unit in the last place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
```

```
.LP
These functions handle special  cases  and exceptions in the same way as the
\fBsqrt()\fR functions  when  \fBc99\fR  \fBMATHERREXCEPT\fR conventions are in
effect. See \fBsqrt\fR(3M) for  the results for special cases.
.sp
.LP
An application wanting to check for exceptions should call
\fBfeclearexcept\fR(\fBFE_ALL_EXCEPT\fR) before calling these functions. On
return, if \fBfetestexcept\fR(\fBFE_INVALID\fR | \fBFE_DIVBYZERO\fR |
\fBFE_OVERFLOW\fR | \fBFE_UNDERFLOW\fR) is non-zero, an exception has been
raised. The application can then examine the result or argument vectors for
exceptional values. Some vector functions can raise the inexact exception even
if all elements of the argument array are such that the numerical results are
exact.

.SH DESCRIPTION
.sp
.LP
These functions compute the magnitude (or modulus) | \fIz\fR | for an entire
vector of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements.
.sp
.LP
Specifically, \fBvz_abs_\fR(\fIn,\fR \fIz\fR, \fIsz\fR, \fIy\fR, \fIsy\fR)
computes \fIy\fR[\fIi\fR * *\fIsy\fR] = | \fIz\fR[\fIi\fR * *\fIsz\fR] | for
each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The  \fBvc_abs_()\fR function performs
the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBcabs\fR(3M) functions given the same arguments.
Non-exceptional results, however, are accurate to within a unit in the last
place.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the

     \fBint *\fR\fIstridez\fR, \fBfloat complex * restrict\fR \fIw\fR, \fBint *\
     \fBfloat *\fR \fItmp\fR);
.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the complex function \fBexp\fR(\fIz\fR) for an entire
vector of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements. The last argument is a pointer to
scratch storage; this storage must be large enough to hold *\fIn\fR consecutive
values of the real type corresponding to the complex type of the argument and
result.
.sp
.LP
Specifically, \fBvz_exp_\fR(\fIn\fR, \fIz\fR, \fIsz\fR, \fIw\fR, \fIsw\fR,
\fItmp\fR) computes \fIw\fR[\fIi\fR * *\fIsw\fR] = \fBexp\fR(\fIz\fR[\fIi\fR *
*\fIsz\fR]) for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvc_exp_()\fR
function performs the same  computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBcexp\fR(3M) functions given the same arguments.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
```

```
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
Unlike the c99 \fBcexp\fR(3M) functions, the vector complex exponential
functions make no attempt to handle special cases and exceptions; they simply
use textbook formulas to compute a complex exponential in terms of real
elementary functions. As a result, these functions can raise different
exceptions and/or deliver different results from \fBcexp()\fR.

.SH NAME
vz_log_, vc_log_ \- vector complex logarithm functions
.SH SYNOPSIS
.LP
.nf
cc [ \fIflag\fR\&.\|.\|. ] \fIfile\fR\&.\|.\|. \fB-lmvec\fR [ \fIlibrary\fR\&.\|

\fBvoid\fR \fBvz_log_\fR(\fBint *\fR\fIn\fR, \fBdouble complex * restrict\fR \fI
     \fBint *\fR\fIstridez\fR, \fBdouble _complex * restrict\fR \fIw\fR, \fBint
.fi

.LP
.nf
\fBvoid\fR \fBvc_log_\fR(\fBint *\fR\fIn\fR, \fBfloat complex * restrict\fR \fIz
     \fBint *\fR\fIstridez\fR, \fBfloat complex * restrict\fR \fIw\fR, \fBint *\
.fi

.SH DESCRIPTION
.sp
.LP
These functions evaluate the complex function \fBlog\fR(\fIz\fR) for an entire
vector of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements.
.sp
.LP
Specifically, \fBvz_log_\fR(\fIn\fR, \fIz\fR, \fIsz\fR, \fIw\fR, \fIsw\fR)
computes \fIw\fR[\fIi\fR * *\fIsw\fR] = \fBlog\fR(\fIz\fR[\fIi\fR * *\fIsz\fR])
for each \fIi\fR = 0, 1, ..., *\fIn\fR - 1. The \fBvc_log_()\fR function
performs the same computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBclog\fR(3M) functions given the same arguments.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
```

```
Unlike the c99 \fBclog\fR(3M) functions, the vector complex exponential
functions make no attempt to handle special cases and exceptions; they simply
use textbook formulas to compute a complex exponential in terms of real
elementary functions. As a result, these functions can raise different
exceptions and/or deliver different results from \fBclog()\fR.

.SH DESCRIPTION
.sp
.LP
These functions evaluate the complex function \fIz\fR^\fIw\fR for an entire
vector of values at once. The first parameter specifies the number of values to
compute. Subsequent parameters specify the argument and result vectors. Each
vector is described by a pointer to the first element and a stride, which is
the increment between successive elements. The last argument is a pointer to
scratch storage; this storage must be large enough to hold 3 * *\fIn\fR
consecutive values of the real type corresponding to the complex type of the
argument and result.
.sp
.LP
Specifically, \fBvz_pow_\fR(\fIn\fR, \fIz\fR, \fIsz\fR, \fIw\fR, \fIsw\fR,
\fIu\fR, \fIsu\fR, \fItmp\fR) computes \fIu\fR[\fIi\fR * *\fIsu\fR] =
(\fIz\fR[\fIi\fR * *\fIsz\fR])^(\fIw\fR[\fIi\fR * *\fIsw\fR]) for each \fIi\fR
= 0, 1, ..., *\fIn\fR - 1. The \fBvc_pow_()\fR function performs the same
computation for single precision data.
.sp
.LP
These functions are not guaranteed to deliver results that are identical to the
results of the \fBcpow\fR(3M) functions given the same arguments.
.SH USAGE
.sp
.LP
The element count *\fIn\fR must be greater than zero. The strides for the
argument and result arrays can be arbitrary integers, but the arrays themselves
must not be the same or overlap. A zero stride effectively collapses an entire
vector into a single element. A negative stride causes a vector to be accessed
in descending memory order, but note that the corresponding pointer must still
point to the first element of the vector to be used; if the stride is negative,
this will be the highest-addressed element in memory. This convention differs
from the Level 1 BLAS, in which array parameters always refer to the
lowest-addressed element in memory even when negative increments are used.
```

```
.sp
.LP
These functions assume that the default round-to-nearest rounding direction
mode is in effect. On x86, these functions also assume that the default
round-to-64-bit rounding precision mode is in effect. The result of calling a
vector function with a non-default rounding mode in effect is undefined.
.sp
.LP
Unlike the c99 \fBcpow\fR(3M) functions, the vector complex exponential
functions make no attempt to handle special cases and exceptions; they simply
use textbook formulas to compute a complex exponential in terms of real
elementary functions. As a result, these functions can raise different
exceptions and/or deliver different results from \fBcpow()\fR.
