#       Note that libcurses installs commands along with its library.
#       This is a minor bug which probably should be fixed.
#       Note also that a few extra libraries are kept in cmd source.
#
# Certain libraries are linked with, hence depend on, other libraries.
#
# Although we have historically used .WAIT to express dependencies, it
# reduces the amount of parallelism and thus lengthens the time it
# takes to build the libraries.  Thus, we now require that any new
# libraries explicitly call out their dependencies.  Eventually, all
# the library dependencies will be called out explicitly.  See
# "Library interdependencies" near the end of this file.
#
# Aside from explicit dependencies (and legacy .WAITs), all libraries
# are built in parallel.
#
.PARALLEL:

533 .KEEP_STATE:

535 #
536 # For the all and install targets, we clearly must respect library
537 # dependencies so that the libraries link correctly.  However, for
538 # the remaining targets (check, clean, clobber, install_h, lint, _dc
539 # and _msg), libraries do not have any dependencies on one another
540 # and thus respecting dependencies just slows down the build.
541 # As such, for these rules, we use pattern replacement to explicitly
542 # avoid triggering the dependency information.  Note that for clean,
543 # clobber and lint, we must use $(NOWAIT_SUBDIRS) rather than
544 # $(SUBDIRS), to prevent '.WAIT' from expanding to '.WAIT-nodepend'.
545 #

 * int __rem_pio2m(x,y,e0,nx,prec,ipio2)
 * double x[],y[]; int e0,nx,prec; const int ipio2[];
 *
 * __rem_pio2m return the last three digits of N with
 *              y = x - N*pi/2
 * so that |y| < pi/4.
 *
 * The method is to compute the integer (mod 8) and fraction parts of
 * (2/pi)*x without doing the full multiplication. In general we
 * skip the part of the product that are known to be a huge integer (
 * more accurately, = 0 mod 8 ). Thus the number of operations are
 * independent of the exponent of the input.
 *
 * (2/PI) is represented by an array of 24-bit integers in ipio2[].
 * Here PI could as well be a machine value pi.
 *
 * Input parameters:
 *      x[]     The input value (must be positive) is broken into nx
 *              pieces of 24-bit integers in double precision format.
 *              x[i] will be the i-th 24 bit of x. The scaled exponent
 *              of x[0] is given in input parameter e0 (i.e., x[0]*2^e0
 *              match x's up to 24 bits.
 *
 *              Example of breaking a double z into x[0]+x[1]+x[2]:
 *                      e0 = ilogb(z)-23
 *                      z  = scalbn(z,-e0)
 *              for i = 0,1,2
 *                      x[i] =  floor(z)
 *                      z    = (z-x[i])*2**24
 *
 *
 *      y[]     ouput result in an array of double precision numbers.
```

```
 *              The dimension of y[] is:
 *                      24-bit  precision       1
 *                      53-bit  precision       2
 *                      64-bit  precision       2
 *                      113-bit precision       3
 *              The actual value is the sum of them. Thus for 113-bit
 *              precsion, one may have to do something like:
 *
 *              long double t,w,r_head, r_tail;
 *              t = (long double)y[2] + (long double)y[1];
 *              w = (long double)y[0];
 *              r_head = t+w;
 *              r_tail = w - (r_head - t);
 *
 *      e0      The exponent of x[0]
 *
 *      nx      dimension of x[]
 *
 *      prec    an interger indicating the precision:
 *                      0       24  bits (single)
 *                      1       53  bits (double)
 *                      2       64  bits (extended)
 *                      3       113 bits (quad)
 *
 *      ipio2[]
 *              integer array, contains the (24*i)-th to (24*i+23)-th
 *              bit of 2/pi or 2/PI after binary point. The corresponding
 *              floating value is
 *
 *                      ipio2[i] * 2^(-24(i+1)).
 *
 * External function:
 *      double scalbn( ), floor( );
 *
 *
 * Here is the description of some local variables:
 *
 *      jk      jk+1 is the initial number of terms of ipio2[] needed
 *              in the computation. The recommended value is 3,4,4,
 *              6 for single, double, extended,and quad.
 *
 *      jz      local integer variable indicating the number of
 *              terms of ipio2[] used.
 *
 *      jx      nx - 1
 *
 *      jv      index for pointing to the suitable ipio2[] for the
 *              computation. In general, we want
 *                      ( 2^e0*x[0] * ipio2[jv-1]*2^(-24jv) )/8
 *              is an integer. Thus
 *                      e0-3-24*jv >= 0 or (e0-3)/24 >= jv
 *              Hence jv = max(0,(e0-3)/24).
 *
 *      jp      jp+1 is the number of terms in pio2[] needed, jp = jk.
 *
 *      q[]     double array with integral value, representing the
 *              24-bits chunk of the product of x and 2/pi.
 *
 *      q0      the corresponding exponent of q[0]. Note that the
 *              exponent for q[i] would be q0-24*i.
 *
 *      pio2[]  double precision array, obtained by cutting pi/2
 *              into 24 bits chunks.
 *
 *      f[]     ipio2[] in floating point
 *
```

```
 *      iq[]    integer array by breaking up q[] in 24-bits chunk.
 *
 *      fq[]    final product of x*(2/pi) in fq[0],..,fq[jk]
 *
 *      ih      integer. If >0 it indicats q[] is >= 0.5, hence
 *              it also indicates the *sign* of the result.

/*LINTLIBRARY*/

/*
 * See /ws/unix200x-gate/usr/src/lib/libc/port/gen/xpg6.c for libc default.
 * __xpg6 (C99/SUSv3) is first included in Solaris 10 libc and libm
 * as well as the K2 (S1S8) libsunmath and libmopt.
 *
 * The default setting, _C99SUSv3_mode_OFF, means to retain current Solaris
 * behavior which is NOT C99/SUSv3 compliant.  This is normal.  These libraries
 * determine which standard to use based on how applications are built.  These
 * libraries at runtime determine which behavior to choose based on the value
 * of __xpg6.  By default they retain their original Solaris behavior.
 *
 * __xpg6 is used to control certain behaviors between the C99 standard, the
 * SUSv3 standard, and Solaris.  More explanation in lib/libc/inc/xpg6.h.
 * The XPG6 C compiler utility (c99) will add an object file that contains
 * an alternate definition for __xpg6.  The symbol interposition provided
 * by the linker will allow these libraries to find that symbol instead.
 *
 * Possible settings are available and documented in lib/libc/inc/xpg6.h.
 */

new/usr/src/lib/libm/common/C/asin.c
In case of |x| < 2**-27 we are talking about x being almost 0.
The graph of arcsine curve shows that arcsin(0) is 0 so we will return 0 if x ==
or return x and generate inexact if x is close to 0.

/*
 * atan(x)
 * Accurate Table look-up algorithm with polynomial approximation in
 * partially product form.
 *
 * -- K.C. Ng, October 17, 2004
 *
 * Algorithm
 *
 * (1). Purge off Inf and NaN and 0
 * (2). Reduce x to positive by atan(x) = -atan(-x).
 * (3). For x <= 1/8 and let z = x*x, return
 *      (2.1) if x < 2^(-prec/2), atan(x) = x  with inexact flag raised
 *      (2.2) if x < 2^(-prec/4-1), atan(x) = x+(x/3)(x*x)
 *      (2.3) if x < 2^(-prec/6-2), atan(x) = x+(z-5/3)(z*x/5)
 *      (2.4) Otherwise
 *              atan(x) = poly1(x) = x + A * B,
 *      where
 *              A = (p1*x*z) * (p2+z(p3+z))
 *              B = (p4+z)+z*z) * (p5+z(p6+z))
 *      Note: (i) domain of poly1 is [0, 1/8], (ii) remez relative
 *      approximation error of poly1 is bounded by
 *               |(atan(x)-poly1(x))/x| <= 2^-57.61
 * (4). For x >= 8 then
 *      (3.1) if x >= 2^prec,     atan(x) = atan(inf) - pio2lo
 *      (3.2) if x >= 2^(prec/3), atan(x) = atan(inf) - 1/x
 *      (3.3) if x <= 65,         atan(x) = atan(inf) - poly1(1/x)
 *      (3.4) otherwise           atan(x) = atan(inf) - poly2(1/x)
 *      where
```

```
 *              poly2(r) = (q1*r) * (q2+z(q3+z)) * (q4+z),
 *      its domain is [0, 0.0154]; and its remez absolute
 *      approximation error is bounded by
 *              |atan(x)-poly2(x)|<= 2^-59.45
 *
 * (5). Now x is in (0.125, 8).
 *      Recall identity
 *              atan(x) = atan(y) + atan((x-y)/(1+x*y)).
 *      Let j = (ix - 0x3fc00000) >> 16, 0 <= j < 96, where ix is the high
 *      part of x in IEEE double format. Then
 *              atan(x) = atan(y[j]) + poly2((x-y[j])/(1+x*y[j]))
 *      where y[j] are carefully chosen so that it matches x to around 4.5
 *      bits and at the same time atan(y[j]) is very close to an IEEE double
 *      floating point number. Calculation indicates that
 *              max|(x-y[j])/(1+x*y[j])| < 0.0154
 *              j,x
 *
 * Accuracy: Maximum error observed is bounded by 0.6 ulp after testing
 * more than 10 million random arguments
 */

/*
 * Let t(0) = 1 and for i = 1, ..., 160, let t(i) be the slope of
 * the line bisecting the conical hull of the set of points (x,y)
 * where x and y are positive normal floating point numbers and
 * the high order words hx and hy of their binary representations
 * satisfy |hx - hy - i * 0x8000| <= 0x4000.  Then:
 *
 * TBL[4*i+2] is t(i) rounded to 21 significant bits (i.e., the
 *   low order word is zero), and
 *
 * TBL[4*i] + TBL[4*i+1] form a doubled-double approximation to
 *   atan(TBL[4*i+2]).
 *
 * Finally, TBL[4*161] = TBL[4*161+1] = TBL[4*161+2] = 0.
 *
 * Now for any (x,y) with 0 < y <= x and any 0 < t <= 1,  we have
 * atan(y/x) = atan(t) + atan((y-t*x)/(x+t*y)).  By choosing t =
 * TBL[4*i+2], where i is the multiple of 0x8000 nearest hx - hy,
 * if this multiple is less than 161, and i = 161 otherwise, we
 * find that |(y-t*x)/(x+t*y)| <~ 2^-5.
 */

/*
 *  cbrt: double precision cube root
 *
 *  Algorithm: bit hacking, table lookup, and polynomial approximation
 *
 *  For normal x, write x = s*2^(3j)*z where s = +/-1, j is an integer,
 *  and 1 <= z < 8.  Let y := s*2^j.  From a table, find u such that
 *  u^3 is computable exactly and |(z-u^3)/u^3| <~ 2^-8.  We construct
 *  y, z, and the table index from x by a few integer operations.
 *
 *  Now cbrt(x) = y*u*(1+t)^(1/3) where t = (z-u^3)/u^3.  We approximate
 *  (1+t)^(1/3) by a polynomial 1+p(t), where p(t) := t*(p1+t*(p2+...+
 *  (p5+t*p6))).  By computing the result as y*(u+u*p(t)), we can bound
 *  the worst case error by .51 ulp.
 *
 *  Notes:
 *
 *  1. For subnormal x, we scale x by 2^54, compute the cube root, and
 *     scale the result by 2^-18.
 *
 *  2. cbrt(+/-inf) = +/-inf and cbrt(NaN) is NaN.

/*
 * cosh(x)
 * Code originated from 4.3bsd.
 * Modified by K.C. Ng for SUN 4.0 libm.
 * Method :
 *      1. Replace x by |x| (cosh(x) = cosh(-x)).
 *      2.
 *                                                      [ exp(x) - 1 ]^2
 *          0       <= x <= 0.3465  :  cosh(x) := 1 + -------------------
 *                                                         2*exp(x)
 *
 *                                                 exp(x) +  1/exp(x)
 *          0.3465  <= x <= 22      :  cosh(x) := -------------------
 *                                                         2
 *          22      <= x <= lnovft  :  cosh(x) := exp(x)/2
 *          lnovft  <= x <  INF     :  cosh(x) := scalbn(exp(x-1024*ln2),1023)
 *
 *      Note: .3465 is a number near one half of ln2.
 *
 * Special cases:
 *      cosh(x) is |x| if x is +INF, -INF, or NaN.
 *      only cosh(0)=1 is exact for finite x.

#pragma weak erf = __erf
#pragma weak erfc = __erfc

/* INDENT OFF */
/* double erf(double x)
 * double erfc(double x)
 *                           x
 *                    2      |\
 *     erf(x)  =  ---------  | exp(-t*t)dt
 *                 sqrt(pi) \|
 *                           0
 *
 *     erfc(x) =  1-erf(x)
 *   Note that
 *              erf(-x) = -erf(x)
 *              erfc(-x) = 2 - erfc(x)
 *
 * Method:
 *      1. For |x| in [0, 0.84375]
 *          erf(x)  = x + x*R(x^2)
 *          erfc(x) = 1 - erf(x)           if x in [-.84375,0.25]
 *                  = 0.5 + ((0.5-x)-x*R)  if x in [0.25,0.84375]
 *         where R = P/Q where P is an odd poly of degree 8 and
 *         Q is an odd poly of degree 10.
 *                                               -57.90
 *                      | R - (erf(x)-x)/x | <= 2
 *
 *
 *         Remark. The formula is derived by noting
 *          erf(x) = (2/sqrt(pi))*(x - x^3/3 + x^5/10 - x^7/42 + ....)
 *         and that
 *          2/sqrt(pi) = 1.128379167095512573896158903121545171688
```

```
 *          is close to one. The interval is chosen because the fix
 *          point of erf(x) is near 0.6174 (i.e., erf(x)=x when x is
 *          near 0.6174), and by some experiment, 0.84375 is chosen to
 *          guarantee the error is less than one ulp for erf.
 *
 *      2. For |x| in [0.84375,1.25], let s = |x| - 1, and
 *         c = 0.84506291151 rounded to single (24 bits)
 *              erf(x)  = sign(x) * (c  + P1(s)/Q1(s))
 *              erfc(x) = (1-c)  - P1(s)/Q1(s) if x > 0
 *                        1+(c+P1(s)/Q1(s))    if x < 0
 *              |P1/Q1 - (erf(|x|)-c)| <= 2**-59.06
 *         Remark: here we use the taylor series expansion at x=1.
 *              erf(1+s) = erf(1) + s*Poly(s)
 *                       = 0.845.. + P1(s)/Q1(s)
 *         That is, we use rational approximation to approximate
 *                      erf(1+s) - (c = (single)0.84506291151)
 *         Note that |P1/Q1|< 0.078 for x in [0.84375,1.25]
 *         where
 *              P1(s) = degree 6 poly in s
 *              Q1(s) = degree 6 poly in s
 *
 *      3. For x in [1.25,1/0.35(~2.857143)],
 *              erfc(x) = (1/x)*exp(-x*x-0.5625+R1/S1)
 *              erf(x)  = 1 - erfc(x)
 *         where
 *              R1(z) = degree 7 poly in z, (z=1/x^2)

/*
 * exp(x)
 * Hybrid algorithm of Peter Tang's Table driven method (for large
 * arguments) and an accurate table (for small arguments).
 * Written by K.C. Ng, November 1988.
 * Method (large arguments):
 *      1. Argument Reduction: given the input x, find r and integer k
 *         and j such that
 *                    x = (k+j/32)*(ln2) + r,  |r| <= (1/64)*ln2
 *
 *      2. exp(x) = 2^k * (2^(j/32) + 2^(j/32)*expm1(r))
 *         a. expm1(r) is approximated by a polynomial:
 *            expm1(r) ~ r + t1*r^2 + t2*r^3 + ... + t5*r^6
 *            Here t1 = 1/2 exactly.
 *         b. 2^(j/32) is represented to twice double precision
 *            as TBL[2j]+TBL[2j+1].
 *
 * Note: If divide were fast enough, we could use another approximation
 *       in 2.a:
 *            expm1(r) ~ (2r)/(2-R), R = r - r^2*(t1 + t2*r^2)
 *            (for the same t1 and t2 as above)
 *
 * Special cases:
 *      exp(INF) is INF, exp(NaN) is NaN;
 *      exp(-INF)=  0;
 *      for finite argument, only exp(0)=1 is exact.
 *
 * Accuracy:
 *      According to an error analysis, the error is always less than
 *      an ulp (unit in the last place).  The largest errors observed
 *      are less than 0.55 ulp for normal results and less than 0.75 ulp
```

```
 *      for subnormal results.
 *
 * Misc. info.
 *      For IEEE double
 *              if x >  7.09782712893383973096e+02 then exp(x) overflow
 *              if x < -7.45133219101941108420e+02 then exp(x) underflow
 */

libm/common/C/expm1.c
For |x| <= 0.5 ln2, (k == 0) we don't need to compute correction (c).
We can initialize c manually with 0, to fix compiler warning.
patch06 - libm: fixed compilation issues after updates

#pragma weak expm1 = __expm1

/* INDENT OFF */
/* expm1(x)
 * Returns exp(x)-1, the exponential of x minus 1.
 *
 * Method
 *   1. Arugment reduction:
 *      Given x, find r and integer k such that
 *
 *                x = k*ln2 + r,  |r| <= 0.5*ln2 ~ 0.34658
 *
 *      Here a correction term c will be computed to compensate
 *      the error in r when rounded to a floating-point number.
 *
 *   2. Approximating expm1(r) by a special rational function on
 *      the interval [0,0.34658]:
 *      Since
 *          r*(exp(r)+1)/(exp(r)-1) = 2+ r^2/6 - r^4/360 + ...
 *      we define R1(r*r) by
 *          r*(exp(r)+1)/(exp(r)-1) = 2+ r^2/6 * R1(r*r)
 *      That is,
 *          R1(r**2) = 6/r *((exp(r)+1)/(exp(r)-1) - 2/r)
 *                   = 6/r * ( 1 + 2.0*(1/(exp(r)-1) - 1/r))
 *                   = 1 - r^2/60 + r^4/2520 - r^6/100800 + ...
 *      We use a special Reme algorithm on [0,0.347] to generate
 *      a polynomial of degree 5 in r*r to approximate R1. The
 *      maximum error of this polynomial approximation is bounded
```

```
 *      by 2**-61. In other words,
 *          R1(z) ~ 1.0 + Q1*z + Q2*z**2 + Q3*z**3 + Q4*z**4 + Q5*z**5
 *      where   Q1  =  -1.66666666666666567384E-2,
 *              Q2  =   3.96825396813703658873E-4,
 *              Q3  =  -9.92063447334359873557E-6,
 *              Q4  =   2.50513614208085170027E-7,
 *              Q5  =  -6.28435056823826171027E-9;
 *      (where z=r*r, and the values of Q1 to Q5 are listed below)
 *      with error bounded by
 *          |                      5           |     -61
 *          | 1.0+Q1*z+...+Q5*z   -  R1(z) | <= 2
 *          |                                  |
 *
 *      expm1(r) = exp(r)-1 is then computed by the following
 *      specific way which minimize the accumulation rounding error:
 *                               2     3
 *                              r     r    [ 3 - (R1 + R1*r/2)  ]
 *            expm1(r) = r + --- + --- * [--------------------]
 *                              2     2    [ 6 - r*(3 - R1*r/2) ]
 *
 *      To compensate the error in the argument reduction, we use
 *              expm1(r+c) = expm1(r) + c + expm1(r)*c
 *                         ~ expm1(r) + c + r*c
 *      Thus c+r*c will be added in as the correction terms for
 *      expm1(r+c). Now rearrange the term to avoid optimization
 *      screw up:
 *                      (     2                                    2 )
 *                      ({  ( r    [ R1 -  (3 - R1*r/2) ]  )  }    r  )
 *       expm1(r+c)~r - ({r*(--- * [--------------------]-c)-c} - --- )
 *                      ({  ( 2    [ 6 - r*(3 - R1*r/2) ]  )  }    2  )
 *                      (                                          )
 *
 *                = r - E
 *   3. Scale back to obtain expm1(x):
 *      From step 1, we have
 *         expm1(x) = either 2^k*[expm1(r)+1] - 1
 *                  = or     2^k*[expm1(r) + (1-2^-k)]
 *   4. Implementation notes:
 *      (A). To save one multiplication, we scale the coefficient Qi
 *           to Qi*2^i, and replace z by (x^2)/2.
 *      (B). To achieve maximum accuracy, we compute expm1(x) by
 *        (i)   if x < -56*ln2, return -1.0, (raise inexact if x!=inf)
 *        (ii)  if k=0, return r-E
 *        (iii) if k=-1, return 0.5*(r-E)-0.5
 *        (iv)  if k=1 if r < -0.25, return 2*((r+0.5)- E)
 *                     else          return  1.0+2.0*(r-E);
 *        (v)   if (k<-2||k>56) return 2^k(1-(E-r)) - 1 (or exp(x)-1)
 *        (vi)  if k <= 20, return 2^k((1-2^-k)-(E-r)), else
 *        (vii) return 2^k(1-((E+2^-k)-r))
 *
 * Special cases:
 *      expm1(INF) is INF, expm1(NaN) is NaN;
 *      expm1(-INF) is -1, and
 *      for finite argument, only expm1(0)=0 is exact.
 *
 * Accuracy:
 *      according to an error analysis, the error is always less than
 *      1 ulp (unit in the last place).
 *
 * Misc. info.
 *      For IEEE double
 *          if x >  7.09782712893383973096e+02 then expm1(x) overflow
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following
 * constants. The decimal values may be used, provided that the
```

```
 * compiler will convert from decimal to binary accurately enough
 * to produce the hexadecimal values shown.

/* INDENT OFF */
/*
 * Hypot(x, y)
 * by K.C. Ng for SUN 4.0 libm, updated 3/11/2003.
 * Method :
 * A. When rounding is rounded-to-nearest:
 *      If z = x * x + y * y has error less than sqrt(2) / 2 ulp than
 *      sqrt(z) has error less than 1 ulp.
 *      So, compute sqrt(x*x+y*y) with some care as follows:
 *      Assume x > y > 0;
 *      1. Check whether save and set rounding to round-to-nearest
 *      2. if x > 2y  use
 *              xh*xh+(y*y+((x-xh)*(x+xh))) for x*x+y*y
 *      where xh = x with lower 32 bits cleared;  else
 *      3. if x <= 2y use
 *              x2h*yh+((x-y)*(x-y)+(x2h*(y-yh)+(x2-x2h)*y))
 *      where x2 = 2*x, x2h = 2x with lower 32 bits cleared, yh = y with
 *      lower 32 bits chopped.
 *
 * B. When rounding is not rounded-to-nearest:
 *      The following (magic) formula will yield an error less than 1 ulp.
 *      z = sqrt(x * x + y * y)
 *              hypot(x, y) = x + (y / ((x + z) / y))
 *
 * NOTE: DO NOT remove parenthsis!
 *
 * Special cases:
 *      hypot(x, y) is INF if x or y is +INF or -INF; else
 *      hypot(x, y) is NAN if x or y is NAN.
 *
 * Accuracy:
 *      hypot(x, y) returns sqrt(x^2+y^2) with error less than 1 ulps
 *      (units in the last place)
 */

/*
 * floating point Bessel's function of the 1st and 2nd kind
 * of order n: jn(n,x),yn(n,x);
 *
 * Special cases:
 *      y0(0)=y1(0)=yn(n,0) = -inf with division by zero signal;
 *      y0(-ve)=y1(-ve)=yn(n,-ve) are NaN with invalid signal.
 * Note 2. About jn(n,x), yn(n,x)
 *      For n=0, j0(x) is called,
 *      for n=1, j1(x) is called,
 *      for n<x, forward recursion us used starting
 *      from values of j0(x) and j1(x).
 *      for n>x, a continued fraction approximation to
 *      j(n,x)/j(n-1,x) is evaluated and then backward
 *      recursion is used starting from a supposed value
 *      for j(n,x). The resulting value of j(0,x) is
 *      compared with the actual value to correct the
 *      supposed value of j(n,x).
 *
 *      yn(n,x) is similar in all respects, except
 *      that forward recursion is used for all
 *      values of n>1.

 *
 *      with remez error |(log(1+f) - P(f))/f| <= 2**-56.81 and
 *
 * (b). For 0.09375 <= x < 24
 *      Use an 8-bit table look-up (3-bit for exponent and 5 bit for
 *      significand):
 *      Let ix stands for the high part of x in IEEE double format.
```

```
 *      Since 0.09375 <= x < 24, we have
 *                    0x3fb80000 <= ix < 0x40380000.
 *      Let j = (ix - 0x3fb80000) >> 15. Then  0 <= j < 256. Choose
 *      a Y[j] such that HIWORD(Y[j]) ~ 0x3fb8400 + (j<<15) (the middle
 *      number between 0x3fb80000 + (j<<15) and 3fb80000 + ((j+1)<<15)),
 *      and at the same time 1/Y[j] as well as log(Y[j]) are very close
 *      to 53-bits floating point numbers.
 *      A table of Y[j], 1/Y[j], and log(Y[j]) are pre-computed and thus
 *              log(x)  = log(Y[j]) + log(1 + (x-Y[j])*(1/Y[j]))
 *                      = log(Y[j]) + log(1 + s)
 *      where
 *              s = (x-Y[j])*(1/Y[j])
 *      We compute max (x-Y[j])*(1/Y[j]) for the chosen Y[j] and obtain
 *      |s| < 0.0154. By applying remez algorithm with Product Polynomial
 *      Approximiation, we find the following approximated of log(1+s)
 *              (b1*s)*(b2+s*(b3+s))*((b4+s*b5)+(s*s)*(b6+s))*(b7+s*(b8+s))
 *      with remez error |log(1+s) - P(s)| <= 2**-63.5
 *
 * (c). Otherwise, get "n", the exponent of x, and then normalize x to
 *      z in [1,2). Then similar to (b) find a Y[i] that matches z to 5.5
 *      significant bits. Then
 *          log(x) = n*ln2 + log(Y[i]) + log(z/Y[i]).
 *
 * Special cases:
 *      log(x) is NaN with signal if x < 0 (including -INF) ;
 *      log(+INF) is +INF; log(0) is -INF with signal;
 *      log(NaN) is that NaN with no signal.
 *
 * Maximum error observed: less than 0.90 ulp
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following constants.
 * The decimal values may be used, provided that the compiler will convert
 * from decimal to binary accurately enough to produce the hexadecimal values
 * shown.

/* INDENT OFF */
/*
 * log10(x) = log(x)/log10
 *
 * Base on Table look-up algorithm with product polynomial
 * approximation for log(x).
 *
 * By K.C. Ng, Nov 29, 2004
 *
 * (a). For x in [1-0.125, 1+0.125], from log.c we have
 *      log(x) =  f + ((a1*f^2) *
 *                ((a2 + (a3*f)*(a4+f)) + (f^3)*(a5+f))) *
 *                (((a6 + f*(a7+f)) + (f^3)*(a8+f)) *
 *                ((a9 + (a10*f)*(a11+f)) + (f^3)*(a12+f)))
 *      where f = x - 1.
 *      (i) modify a1 <- a1 / log10
 *      (ii) 1/log10 = 0.4342944819...
 *                   = 0.4375 - 0.003205518... (7 bit shift)
 *           Let lgv = 0.4375 - 1/log10, then
 *           lgv = 0.00320551809674817234887108108339 5...,
 *      (iii) f*0.4375 is exact because f has 3 trailing zero.
 *      (iv) Thus, log10(x) = f*0.4375 - (lgv*f - PPoly)
 *
 * (b). For 0.09375 <= x < 24
 *      Let j = (ix - 0x3fb80000) >> 15. Look up Y[j], 1/Y[j], and log(Y[j])
 *      from _TBL_log.c. Then
 *             log10(x)  = log10(Y[j]) + log10(1 + (x-Y[j])*(1/Y[j]))
 *                       = log(Y[j])(1/log10) + log10(1 + s)
 *      where
 *             s = (x-Y[j])*(1/Y[j])
 *      From log.c, we have log(1+s) =
```

```
 *                                2             2                    2
 *             (b s) (b + b s + s ) [b + b s + s (b + s)] (b + b s + s )
 *               1     2   3          4   5        6        7   8
 *
 *      By setting b1 <- b1/log10, we have
 *             log10(x) = 0.4375 * T - (lgv * T - POLY(s))
 *
 * (c). Otherwise, get "n", the exponent of x, and then normalize x to
 *      z in [1,2). Then similar to (b) find a Y[i] that matches z to 5.5
 *      significant bits. Then
 *          log(x) = n*ln2 + log(Y[i]) + log(z/Y[i]).
 *          log10(x) = n*(ln2/ln10) + log10(z).
 *
 * Special cases:
 *      log10(x) is NaN with signal if x < 0 (including -INF) ;
 *      log10(+INF) is +INF; log10(0) is -INF with signal;
 *      log10(NaN) is that NaN with no signal.
 *
 * Maximum error observed: less than 0.89 ulp

#pragma weak log1p = __log1p

/* INDENT OFF */
/*
 * Method :
 *   1. Argument Reduction: find k and f such that
 *                      1+x = 2^k * (1+f),
 *         where  sqrt(2)/2 < 1+f < sqrt(2) .
 *
 *      Note. If k=0, then f=x is exact. However, if k!=0, then f
 *      may not be representable exactly. In that case, a correction
 *      term is need. Let u=1+x rounded. Let c = (1+x)-u, then
 *      log(1+x) - log(u) ~ c/u. Thus, we proceed to compute log(u),
 *      and add back the correction term c/u.
 *      (Note: when x > 2**53, one can simply return log(x))
 *
 *   2. Approximation of log1p(f).
 *      Let s = f/(2+f) ; based on log(1+f) = log(1+s) - log(1-s)
 *               = 2s + 2/3 s**3 + 2/5 s**5 + .....,
 *               = 2s + s*R
 *      We use a special Reme algorithm on [0,0.1716] to generate
 *      a polynomial of degree 14 to approximate R The maximum error
 *      of this polynomial approximation is bounded by 2**-58.45. In
 *      other words,
 *                      2      4      6      8      10      12      14
 *          R(z) ~ Lp1*s +Lp2*s +Lp3*s +Lp4*s +Lp5*s  +Lp6*s  +Lp7*s
 *      (the values of Lp1 to Lp7 are listed in the program)
 *      and
 *          |      2          14          |     -58.45
```

```
 *          | Lp1*s +...+Lp7*s    -  R(z) | <= 2
 *          |                             |
 *      Note that 2s = f - s*f = f - hfsq + s*hfsq, where hfsq = f*f/2.
 *      In order to guarantee error in log below 1ulp, we compute log
 *      by
 *              log1p(f) = f - (hfsq - s*(hfsq+R)).
 *
 *      3. Finally, log1p(x) = k*ln2 + log1p(f).
 *                           = k*ln2_hi+(f-(hfsq-(s*(hfsq+R)+k*ln2_lo)))
 *         Here ln2 is splitted into two floating point number:
 *                      ln2_hi + ln2_lo,
 *         where n*ln2_hi is always exact for |n| < 2000.
 *
 * Special cases:
 *      log1p(x) is NaN with signal if x < -1 (including -INF) ;
 *      log1p(+INF) is +INF; log1p(-1) is -INF with signal;
 *      log1p(NaN) is that NaN with no signal.
 *
 * Accuracy:
 *      according to an error analysis, the error is always less than
 *      1 ulp (unit in the last place).
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following
 * constants. The decimal values may be used, provided that the
 * compiler will convert from decimal to binary accurately enough
 * to produce the hexadecimal values shown.
 *
 * Note: Assuming log() return accurate answer, the following
 *       algorithm can be used to compute log1p(x) to within a few ULP:
 *
 *              u = 1+x;
 *              if(u==1.0) return x ; else
 *                         return log(u)*(x/(u-1.0));
 *
 *       See HP-15C Advanced Functions Handbook, p.193.

 *
 * Base on Table look-up algorithm with product polynomial
 * approximation for log(x).
 *
 * By K.C. Ng, Nov 29, 2004
 *
 * (a). For x in [1-0.125, 1+0.125], from log.c we have
 *      log(x) =  f + ((a1*f^2) *
 *                ((a2 + (a3*f)*(a4+f)) + (f^3)*(a5+f))) *
 *                (((a6 + f*(a7+f)) + (f^3)*(a8+f)) *
 *                ((a9 + (a10*f)*(a11+f)) + (f^3)*(a12+f)))
 *      where f = x - 1.
 *      (i) modify a1 <- a1 / log2
 *      (ii) 1/log2 = 1.4426950408889634...
 *                  = 1.5 - 0.057304959... (4 bit shift)
 *           Let lv = 1.5 - 1/log2, then
 *           lv = 0.05730495911103659264007531899810795666532 5,
 *      (iii) f*1.5 is exact because f has 3 trailing zero.
 *      (iv) Thus, log2(x) = f*1.5 - (lv*f - PPoly)
 *
 * (b). For 0.09375 <= x < 24
 *      Let j = (ix - 0x3fb80000) >> 15. Look up Y[j], 1/Y[j], and log(Y[j])
 *      from _TBL_log.c. Then
 *              log2(x)  = log2(Y[j]) + log2(1 + (x-Y[j])*(1/Y[j]))
 *                       = log(Y[j])(1/log2) + log2(1 + s)
 *      where
 *              s = (x-Y[j])*(1/Y[j])
```

```
 *      From log.c, we have log(1+s) =
 *                                 2                2                   2
 *             (b s) (b + b s + s ) [b + b s + s (b + s)] (b + b s + s )
 *               1     2   3          4   5        6        7   8
 *
 *      By setting b1 <- b1/log2, we have
 *             log2(x) = 1.5 * T - (lv * T - POLY(s))
 *
 * (c). Otherwise, get "n", the exponent of x, and then normalize x to
 *      z in [1,2). Then similar to (b) find a Y[i] that matches z to 5.5
 *      significant bits. Then
 *          log2(x) = n + log2(z).
 *
 * Special cases:
 *      log2(x) is NaN with signal if x < 0 (including -INF) ;
 *      log2(+INF) is +INF; log2(0) is -INF with signal;
 *      log2(NaN) is that NaN with no signal.
 *
 * Maximum error observed: less than 0.84 ulp
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following constants.
 * The decimal values may be used, provided that the compiler will convert
 * from decimal to binary accurately enough to produce the hexadecimal values
 * shown.

/*
 * pow(x,y) return x**y
 *                      n
 * Method:  Let x =  2   * (1+f)
 *      1. Compute and return log2(x) in two pieces:
 *              log2(x) = w1 + w2,
 *         where w1 has 24 bits trailing zero.
 *      2. Perform y*log2(x) by simulating muti-precision arithmetic
 *      3. Return x**y = exp2(y*log(x))
 *
 * Special cases:
 *      1.  (anything) ** +-0 is 1
 *      1'. 1 ** (anything)   is 1      (C99; 1 ** +-INF/NAN used to be NAN)
 *      2.  (anything) ** 1   is itself
 *      3.  (anything except 1) ** NAN is NAN ("except 1" is C99)
 *      4.  NAN ** (anything except 0) is NAN
 *      5.  +-(|x| > 1) **  +INF is +INF
 *      6.  +-(|x| > 1) **  -INF is +0
 *      7.  +-(|x| < 1) **  +INF is +0
 *      8.  +-(|x| < 1) **  -INF is +INF
 *      9.  -1              ** +-INF is 1   (C99; -1 ** +-INF used to be NAN)
 *      10. +0 ** (+anything except 0, NAN)               is +0
 *      11. -0 ** (+anything except 0, NAN, odd integer)  is +0
 *      12. +0 ** (-anything except 0, NAN)               is +INF
 *      13. -0 ** (-anything except 0, NAN, odd integer)  is +INF
 *      14. -0 ** (odd integer) = -( +0 ** (odd integer) )
 *      15. +INF ** (+anything except 0,NAN) is +INF
```

```
 *      16. +INF ** (-anything except 0,NAN) is +0
 *      17. -INF ** (anything)  = -0 ** (-anything)
 *      18. (-anything) ** (integer) is (-1)**(integer)*(+anything**integer)
 *      19. (-anything except 0 and inf) ** (non-integer) is NAN
 *
 * Accuracy:
 *      pow(x,y) returns x**y nearly rounded. In particular
 *                      pow(integer,integer)
 *      always returns the correct integer provided it is representable.

/*
 * sincos(x,s,c)
 * Accurate Table look-up algorithm by K.C. Ng, 2000.
 *
 * 1. Reduce x to x>0 by cos(-x)=cos(x), sin(-x)=-sin(x).
 * 2. For 0<= x < 8, let i = (64*x chopped)-10. Let d = x - a[i], where
 *    a[i] is a double that is close to (i+10.5)/64 (and hence |d|< 10.5/64)
 *    and such that sin(a[i]) and cos(a[i]) is close to a double (with error
 *    less than 2**-8 ulp). Then
 *
 *      cos(x) = cos(a[i]+d) = cos(a[i])cos(d) - sin(a[i])*sin(d)
 *             = TBL_cos_a[i]*(1+QQ1*d^2+QQ2*d^4) -
 *                       TBL_sin_a[i]*(d+PP1*d^3+PP2*d^5)
 *             = TBL_cos_a[i] + (TBL_cos_a[i]*d^2*(QQ1+QQ2*d^2) -
 *                       TBL_sin_a[i]*(d+PP1*d^3+PP2*d^5))
 *
 *      sin(x) = sin(a[i]+d) = sin(a[i])cos(d) + cos(a[i])*sin(d)
 *             = TBL_sin_a[i]*(1+QQ1*d^2+QQ2*d^4) +
 *                       TBL_cos_a[i]*(d+PP1*d^3+PP2*d^5)
 *             = TBL_sin_a[i] + (TBL_sin_a[i]*d^2*(QQ1+QQ2*d^2) +
 *                       TBL_cos_a[i]*(d+PP1*d^3+PP2*d^5))
 *
 *    Note: for x close to n*pi/2, special treatment is need for either
 *    sin or cos:
 *    i in [81, 100] (  pi/2 +-10.5/64 => tiny cos(x) = sin(pi/2-x)
 *    i in [181,200] (  pi   +-10.5/64 => tiny sin(x) = sin(pi-x)
 *    i in [282,301] (  3pi/2+-10.5/64 => tiny cos(x) = sin(x-3pi/2)
 *    i in [382,401] (  2pi  +-10.5/64 => tiny sin(x) = sin(x-2pi)
 *    i in [483,502] (  5pi/2+-10.5/64 => tiny cos(x) = sin(5pi/2-x)
 *
```

```
 * 3. For x >= 8.0, use kernel function __rem_pio2 to perform argument
 *    reduction and call __k_sincos_ to compute sin and cos.
 *
 * kernel function:
 *      __rem_pio2      ... argument reduction routine
 *      __k_sincos_     ... sine and cosine function on [-pi/4,pi/4]
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C           -S            -C/S
 *          2          -S          -C            S/C
 *          3          -C          S             -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
 *      TRIG(x) returns trig(x) nearly rounded (less than 1 ulp)
 */

 * RETURN THE HYPERBOLIC TANGENT OF X
 * code based on 4.3bsd
 * Modified by K.C. Ng for sun 4.0, Jan 31, 1987
 *
 * Method :
 *      1. reduce x to non-negative by tanh(-x) = - tanh(x).
 *      2.
 *          0      <  x <=  1.e-10 :  tanh(x) := x
 *                                                -expm1(-2x)
 *          1.e-10 <  x <=  1      :  tanh(x) := --------------
 *                                               expm1(-2x) + 2
 *                                                     2
 *          1      <= x <=  22.0   :  tanh(x) := 1 -  ---------------
 *                                                    expm1(2x) + 2
 *          22.0   <  x <= INF     :  tanh(x) := 1.
 *
 *      Note: 22 was chosen so that fl(1.0+2/(expm1(2*22)+2)) == 1.
 *
 * Special cases:
 *      tanh(NaN) is NaN;
 *      only tanh(0)=0 is exact for finite argument.

/* long double __k_lgammal(long double x, int *signgamlp);
 * K.C. Ng, August, 1989.
 *
 * We choose [1.5,2.5] to be the primary interval. Our algorithms
 * are mainly derived from
 *
 *
 *                              zeta(2)-1    2    zeta(3)-1    3
 * lgamma(2+s) = s*(1-euler) + --------- * s  -  --------- * s  + ...
 *                                 2                 3
 *
 *
 * Note 1. Since gamma(1+s)=s*gamma(s), hence
 *              lgamma(1+s) = log(s) + lgamma(s), or
 *              lgamma(s) = lgamma(1+s) - log(s).
 *         When s is really tiny (like roundoff), lgamma(1+s) ~ s(1-enler)
 *         Hence lgamma(s) ~ -log(s) for tiny s
 *

/* long double function erf,erfc (long double x)
 * K.C. Ng, September, 1989.
 *                           x
 *                    2      |\
 *     erf(x)  =  ---------  | exp(-t*t)dt
 *                 sqrt(pi) \|
 *                           0
 *
 *     erfc(x) =  1-erf(x)
 *
 * method:
 *      Since erf(-x) = -erf(x), we assume x>=0.
 *      For x near 0, we have the expansion
 *
 *          erf(x) = (2/sqrt(pi))*(x - x^3/3 + x^5/10 - x^7/42 + ....).
 *
 *      Since 2/sqrt(pi) = 1.128379167095512573896158903121545171688,
 *      we use x + x*P(x^2) to approximate erf(x). This formula will
 *      guarantee the error less than one ulp where x is not too far
 *      away from 0. We note that erf(x)=x at x = 0.6174..... After
 *      some experiment, we choose the following approximation on
 *      interval [0,0.84375].
 *
 *      For x in [0,0.84375]
 *                 2               2        4              40
 *         P =  P(x ) = (p0 + p1 * x + p2 * x + ... + p20 * x  )
 *
 *         erf(x)  = x + x*P
 *         erfc(x) = 1 - erf(x)           if x<=0.25
 *                 = 0.5 + ((0.5-x)-x*P)  if x in [0.25,0.84375]
 *      precision: |P(x^2)-(erf(x)-x)/x| <= 2**-122.50
 *
```

```
 *      For x in [0.84375,1.25], let s = x - 1, and
 *      c = 0.84506291151 rounded to single (24 bits)
 *         erf(x)  = c  + P1(s)/Q1(s)
 *         erfc(x) = (1-c)  - P1(s)/Q1(s)
 *      precision: |P1/Q1 - (erf(x)-c)| <= 2**-118.41
 *
 *
 *      For x in [1.25,1.75], let s = x - 1.5, and
 *      c = 0.95478588343 rounded to single (24 bits)
 *         erf(x)  = c  + P2(s)/Q2(s)
 *         erfc(x) = (1-c)  - P2(s)/Q2(s)
 *      precision: |P1/Q1 - (erf(x)-c)| <= 2**-123.83
 *
 *
 *      For x in [1.75,16/3]
 *         erfc(x) = exp(-x*x)*(1/x)*R1(1/x)/S1(1/x)
 *         erf(x)  = 1 - erfc(x)
 *      precision: absolute error of R1/S1 is bounded by 2**-124.03
 *
 *      For x in [16/3,107]
 *         erfc(x) = exp(-x*x)*(1/x)*R2(1/x)/S2(1/x)
 *         erf(x)  = 1 - erfc(x) (if x>=9 simple return erf(x)=1 with inexact)
 *      precision: absolute error of R2/S2 is bounded by 2**-120.07
 *
 *      Else if inf > x >= 107
 *         erf(x)  = 1 with inexact
 *         erfc(x) = 0 with underflow
 *
 *      Special case:
 *         erf(inf)  = 1
 *         erfc(inf) = 0

#if defined(ELFOBJ)
#pragma weak hypotl = __hypotl
#endif

/*
 * hypotl(x,y)
 * Method :
 *      If z=x*x+y*y has error less than sqrt(2)/2 ulp than sqrt(z) has
 *      error less than 1 ulp.
 *      So, compute sqrt(x*x+y*y) with some care as follows:
 *      Assume x>y>0;
 *      1. save and set rounding to round-to-nearest
 *      2. if x > 2y  use
 *              x1*x1+(y*y+(x2*(x+x2))) for x*x+y*y
 *      where x1 = x with lower 32 bits cleared, x2 = x-x1; else
 *      3. if x <= 2y use
 *              t1*y1+((x-y)*(x-y)+(t1*y2+t2*y))
 *      where t1 = 2x with lower 64 bits cleared, t2 = 2x-t1, y1= y with
 *      lower 32 bits cleared, y2 = y-y1.
 *
 *      NOTE: DO NOT remove parenthsis!
 *
 * Special cases:
 *      hypot(x,y) is INF if x or y is +INF or -INF; else
 *      hypot(x,y) is NAN if x or y is NAN.
 *
 * Accuracy:
 *      hypot(x,y) returns sqrt(x^2+y^2) with error less than 1 ulps (units
 *      in the last place)
 */

/*
 * floating point Bessel's function of the 1st and 2nd kind
 * of order n: jn(n,x),yn(n,x);
 *
 * Special cases:
 *      y0(0)=y1(0)=yn(n,0) = -inf with division by zero signal;
 *      y0(-ve)=y1(-ve)=yn(n,-ve) are NaN with invalid signal.
 * Note 2. About jn(n,x), yn(n,x)
 *      For n=0, j0(x) is called,
 *      for n=1, j1(x) is called,
 *      for n<x, forward recursion us used starting
 *      from values of j0(x) and j1(x).
 *      for n>x, a continued fraction approximation to
 *      j(n,x)/j(n-1,x) is evaluated and then backward
 *      recursion is used starting from a supposed value
 *      for j(n,x). The resulting value of j(0,x) is
 *      compared with the actual value to correct the
 *      supposed value of j(n,x).
 *
 *      yn(n,x) is similar in all respects, except
 *      that forward recursion is used for all
 *      values of n>1.
 *

#pragma weak sincosl = __sincosl

/* INDENT OFF */
/* cosl(x)
 * Table look-up algorithm by K.C. Ng, November, 1989.
 *
 * kernel function:
 *      __k_sincosl     ... sin and cos function on [-pi/4,pi/4]
 *      __rem_pio2l     ... argument reduction routine
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C          -S            -C/S
 *          2         -S          -C             S/C
 *          3         -C           S            -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
 *      computer TRIG(x) returns trig(x) nearly rounded.
```

#pragma weak sinl = __sinl

/* INDENT OFF */
/* sinl(x)
 * Table look-up algorithm by K.C. Ng, November, 1989.
 *
 * kernel function:
 *      __k_sinl                ... sin function on [-pi/4,pi/4]
 *      __k_cosl                ... cos function on [-pi/4,pi/4]
 *      __rem_pio2l     ... argument reduction routine
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C          -S            -C/S
 *          2         -S          -C             S/C
 *          3         -C           S            -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
```

```
 *      computer TRIG(x) returns trig(x) nearly rounded.

/*
 * long double __k_lgammal(long double x, int *signgamlp);
 * K.C. Ng, August, 1989.
 *
 * We choose [1.5,2.5] to be the primary interval. Our algorithms
 * are mainly derived from
 *
 *
 *                              zeta(2)-1    2    zeta(3)-1    3
 * lgamma(2+s) = s*(1-euler) + --------- * s  -  --------- * s  + ...
 *                                 2               3
 *
 *
 * Note 1. Since gamma(1+s)=s*gamma(s), hence
 *              lgamma(1+s) = log(s) + lgamma(s), or
 *              lgamma(s) = lgamma(1+s) - log(s).
 *         When s is really tiny (like roundoff), lgamma(1+s) ~ s(1-enler)
 *         Hence lgamma(s) ~ -log(s) for tiny s
 *

/*
 * atan2l(y,x)
 *
 * Method :
 *      1. Reduce y to positive by atan2(y,x)=-atan2(-y,x).
 *      2. Reduce x to positive by (if x and y are unexceptional):
 *              ARG (x+iy) = arctan(y/x)           ... if x > 0,
 *              ARG (x+iy) = pi - arctan[y/(-x)]   ... if x < 0,
 *
 * Special cases:
 *
 *      ATAN2((anything), NaN ) is NaN;
 *      ATAN2(NAN , (anything) ) is NaN;
 *      ATAN2(+-0, +(anything but NaN)) is +-0  ;
 *      ATAN2(+-0, -(anything but NaN)) is +-PI ;
 *      ATAN2(+-(anything but 0 and NaN), 0) is +-PI/2;
 *      ATAN2(+-(anything but INF and NaN), +INF) is +-0 ;
 *      ATAN2(+-(anything but INF and NaN), -INF) is +-PI;
 *      ATAN2(+-INF,+INF ) is +-PI/4 ;
 *      ATAN2(+-INF,-INF ) is +-3PI/4;
 *      ATAN2(+-INF, (anything but,0,NaN, and INF)) is +-PI/2;
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following constants.
 * The decimal values may be used, provided that the compiler will convert
 * from decimal to binary accurately enough to produce the hexadecimal values
 * shown.
 */

#pragma weak atanl = __atanl

/*
 * atanl(x)
 * Table look-up algorithm
 * By K.C. Ng, March 9, 1989
 *
 * Algorithm.
 *
 * The algorithm is based on atan(x)=atan(y)+atan((x-y)/(1+x*y)).
 * We use poly1(x) to approximate atan(x) for x in [0,1/8] with
 * error (relative)
 *      |(atan(x)-poly1(x))/x|<= 2^-115.94      long double
 *      |(atan(x)-poly1(x))/x|<= 2^-58.85       double
 *      |(atan(x)-poly1(x))/x|<= 2^-25.53       float
 * and use poly2(x) to approximate atan(x) for x in [0,1/65] with
 * error (absolute)
 *      |atan(x)-poly2(x)|<= 2^-122.15          long double
 *      |atan(x)-poly2(x)|<= 2^-64.79           double
 *      |atan(x)-poly2(x)|<= 2^-35.36           float
 * Here poly1 and poly2 are odd polynomial with the following form:
 *              x + x^3*(a1+x^2*(a2+...))
 *
 * (0). Purge off Inf and NaN and 0
 * (1). Reduce x to positive by atan(x) = -atan(-x).
 * (2). For x <= 1/8, use
 *      (2.1) if x < 2^(-prec/2-2), atan(x) =  x  with inexact
 *      (2.2) Otherwise
 *              atan(x) = poly1(x)
 * (3). For x >= 8 then
 *      (3.1) if x >= 2^(prec+2),   atan(x) = atan(inf) - pio2lo
 *      (3.2) if x >= 2^(prec/3+2), atan(x) = atan(inf) - 1/x
```

```
 *      (3.3) if x >  65,           atan(x) = atan(inf) - poly2(1/x)
 *      (3.4) Otherwise,            atan(x) = atan(inf) - poly1(1/x)
 *
 * (4). Now x is in (0.125, 8)
 *      Find y that match x to 4.5 bit after binary (easy).
 *      If iy is the high word of y, then
 *              single : j = (iy - 0x3e000000) >> 19
 *              double : j = (iy - 0x3fc00000) >> 16
 *              quad   : j = (iy - 0x3ffc0000) >> 12
 *
 *      Let s = (x-y)/(1+x*y). Then
 *      atan(x) = atan(y) + poly1(s)
 *              = _TBL_atanl_hi[j] + (_TBL_atanl_lo[j] + poly2(s) )
 *
 *      Note. |s| <= 1.5384615385e-02 = 1/65. Maxium occurs at x = 1.03125
 *
 */

 * cosl(x)
 * Table look-up algorithm by K.C. Ng, November, 1989.
 *
 * kernel function:
 *      __k_sinl        ... sin function on [-pi/4,pi/4]
 *      __k_cosl        ... cos function on [-pi/4,pi/4]
 *      __rem_pio2l     ... argument reduction routine
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C          -S            -C/S
 *          2         -S          -C             S/C
 *          3         -C           S            -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
 *      computer TRIG(x) returns trig(x) nearly rounded.
 */

         * Note that exp(-x*x+d) = exp(-x*x)*exp(d), so to compute
         * exp(-x*x) with a small relative error, we need to compute
         * -x*x with a small absolute error.  To this end, we set y
         * equal to the leading part of x but with enough trailing
         * zeros that y*y can be computed exactly and we rewrite x*x
         * as y*y + (x-y)*(x+y), distributing the latter expression
         * across the exponential.
         *
         * We could construct y in a portable way by setting
         *
         *   int i = (int)(x * ptwo);
         *   y = (long double)i * 1/ptwo;
         *
         * where ptwo is some power of two large enough to make x-y
         * small but not so large that the conversion to int overflows.
         * When long double arithmetic is slow, however, the following
         * non-portable code is preferable.
         */
        y = x;
        *(2+(int*)&y) = *(3+(int*)&y) = 0;
        t *= expl(-y*y)*expl(-(x-y)*(x+y));
        return  t;
}
```

/*
 * expl(x)
 * Table driven method
 * Written by K.C. Ng, November 1988.
 * Algorithm :
 *      1. Argument Reduction: given the input x, find r and integer k
 *         and j such that
 *                    x = (32k+j)*ln2 + r,  |r| <= (1/64)*ln2 .
 *
 *      2. expl(x) = 2^k * (2^(j/32) + 2^(j/32)*expm1(r))
 *         Note:
 *         a. expm1(r) = (2r)/(2-R), R = r - r^2*(t1 + t2*r^2)
 *         b. 2^(j/32) is represented as
 *                      _TBL_expl_hi[j]+_TBL_expl_lo[j]
 *         where
 *              _TBL_expl_hi[j] = 2^(j/32) rounded
 *              _TBL_expl_lo[j] = 2^(j/32) - _TBL_expl_hi[j].
 *
 * Special cases:
 *      expl(INF) is INF, expl(NaN) is NaN;
 *      expl(-INF)=  0;
 *      for finite argument, only expl(0)=1 is exact.
 *
 * Accuracy:
 *      according to an error analysis, the error is always less than
 *      an ulp (unit in the last place).
 *
 * Misc. info.
 *      For 113 bit long double
 *              if x >  1.13565234062941439494919310779707634284 5e+4
 *      then expl(x) overflow;
 *              if x < -1.14334627433362978788372438434526215034 1e+4
 *      then expl(x) underflow
 *
 * Constants:
 * Only decimal values are given. We assume that the compiler will convert
 * from decimal to binary accurately enough to produce the correct
 * hexadecimal values.
 */

 *      3. For 1/16 < |x| < 1.125, choose x(+-i) ~ +-(i+4.5)/64, i=0,..,67
```

```
 *         since
 *              exp(x) = exp(xi+(x-xi))= exp(xi)*exp((x-xi))
 *         we have
 *              expm1(x) = expm1(xi)+(exp(xi))*(expm1(x-xi))
 *         where
 *              |s=x-xi| <= 1/128
 *         and
 *      expm1(s)=2s/(2-R), R= s-s^2*(T1+s^2*(T2+s^2*(T3+s^2*(T4+s^2*T5))))
 *
 * T1 =   1.66666666666666666666666666660876387437e-1L,
 * T2 =  -2.77777777777777777777770781209317347875 6e-3L,
 * T3 =   6.61375661375661348207428093287422120 2424e-5L,
 * T4 =  -1.65343915339213995416960982274223585112 0e-6L,
 * T5 =   4.17531485176953975138785211661097379605 3e-8L;
 *
 *      4. For |x| >= 1.125, return exp(x)-1.
 *         (see algorithm for exp)
 *
 * Special cases:
 *      expm1l(INF) is INF, expm1l(NaN) is NaN;
 *      expm1l(-INF)= -1;
 *      for finite argument, only expm1l(0)=0 is exact.
 *
 * Accuracy:
 *      according to an error analysis, the error is always less than
 *      2 ulp (unit in the last place).
 *
 * Misc. info.
 *      For 113 bit long double
 *              if x >  1.13565234062941439494919310779707634284 5e+4
 *      then expm1l(x) overflow;
 *
 * Constants:
 * Only decimal values are given. We assume that the compiler will convert
 * from decimal to binary accurately enough to produce the correct
 * hexadecimal values.

#pragma weak hypotl = __hypotl

/*
 * long double hypotl(long double x, long double y);
 * Method :
 *      If z=x*x+y*y has error less than sqrt(2)/2 ulp than sqrt(z) has
 *      error less than 1 ulp.
 *      So, compute sqrt(x*x+y*y) with some care as follows:
 *      Assume x>y>0;
 *      1. save and set rounding to round-to-nearest
 *      2. if x > 2y  use
 *              x1*x1+(y*y+(x2*(x+x2))) for x*x+y*y
 *      where x1 = x with lower 64 bits cleared, x2 = x-x1; else
 *      3. if x <= 2y use
 *              t1*y1+((x-y)*(x-y)+(t1*y2+t2*y))
 *      where t1 = 2x with lower 64 bits cleared, t2 = 2x-t1, y1= y with
 *      lower 64 bits chopped, y2 = y-y1.
 *
 *      NOTE: DO NOT remove parenthsis!
 *
 * Special cases:
 *      hypot(x,y) is INF if x or y is +INF or -INF; else
 *      hypot(x,y) is NAN if x or y is NAN.
 *
 * Accuracy:
 *      hypot(x,y) returns sqrt(x^2+y^2) with error less than 1 ulps (units
 *      in the last place)

/*
 * floating point Bessel's function of the 1st and 2nd kind
 * of order n: jn(n,x),yn(n,x);
 *
 * Special cases:
 *      y0(0)=y1(0)=yn(n,0) = -inf with division by zero signal;
 *      y0(-ve)=y1(-ve)=yn(n,-ve) are NaN with invalid signal.
 * Note 2. About jn(n,x), yn(n,x)
 *      For n=0, j0(x) is called,
 *      for n=1, j1(x) is called,
 *      for n<x, forward recursion us used starting
 *      from values of j0(x) and j1(x).
 *      for n>x, a continued fraction approximation to
 *      j(n,x)/j(n-1,x) is evaluated and then backward
 *      recursion is used starting from a supposed value
 *      for j(n,x). The resulting value of j(0,x) is
 *      compared with the actual value to correct the
 *      supposed value of j(n,x).
 *
 *      yn(n,x) is similar in all respects, except
 *      that forward recursion is used for all
 *      values of n>1.
 *

 *              if(n<0)  n = n+1;
 *              x = scalbn(x,-n);
 *              LOG10(x) := n*log10_2hi + (n*log10_2lo + ivln10*log(x))
 *
 * Note1:
 *      For fear of destroying log10(10**n)=n, the rounding mode is
 *      set to Round-to-Nearest.
 *
 * Special cases:
 *      log10(x) is NaN with signal if x < 0;
 *      log10(+INF) is +INF with no signal; log10(0) is -INF with signal;
 *      log10(NaN) is that NaN with no signal;
 *      log10(10**N) = N  for N=0,1,...,22.
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following constants.
 * The decimal values may be used, provided that the compiler will convert
 * from decimal to binary accurately enough to produce the hexadecimal values
```

/*
 * log1pl(x)
 * Table look-up algorithm by modifying logl.c
 * By K.C. Ng, July 6, 1995
 *
 * (a). For 1+x in [31/33,33/31], using a special approximation:
 *      s = x/(2.0+x);  ... here |s| <= 0.03125
 *      z = s*s;
 *      return x-s*(x-z*(B1+z*(B2+z*(B3+z*(B4+...+z*B9)...))));
 *      (i.e., x is in [-2/33,2/31])
 *
 * (b). Otherwise, normalize 1+x = 2^n * 1.f.
 *      Here we may need a correction term for 1+x rounded.
 *      Use a 6-bit table look-up: find a 6 bit g that match f to 6.5 bits,
 *      then
 *          log(1+x) = n*ln2 + log(1.g) + log(1.f/1.g).
 *      Here the leading and trailing values of log(1.g) are obtained from
 *      a size-64 table.
 *      For log(1.f/1.g), let s = (1.f-1.g)/(1.f+1.g). Note that
 *              1.f = 2^-n(1+x)
```

```
 *
 *      then
 *          log(1.f/1.g) = log((1+s)/(1-s)) = 2s + 2/3 s^3 + 2/5 s^5 +...
 *      Note that |s|<2**-8=0.00390625. We use an odd s-polynomial
 *      approximation to compute log(1.f/1.g):
 *              s*(A1+s^2*(A2+s^2*(A3+s^2*(A4+s^2*(A5+s^2*(A6+s^2*A7))))))
 *      (Precision is 2**-136.91 bits, absolute error)
 *
 *      CAUTION:
 *      For x>=1, compute 1+x will lost one bit (OK).
 *      For x in [-0.5,-1), 1+x is exact.
 *      For x in (-0.5,-2/33]U[2/31,1), up to 4 last bits of x will be lost
 *      in 1+x.  Therefore, to recover the lost bits, one need to compute
 *      1.f-1.g accurately.
 *
 *      Let hx = HI(x), m = (hx>>16)-0x3fff (=ilogbl(x)), note that
 *              -2/33 = -0.0606...= 2^-5 * 1.939...,
 *               2/31 =  0.09375  = 2^-4 * 1.500...,
 *      so for x in (-0.5,-2/33], -5<=m<=-2,  n= -1, 1+f=2*(1+x)
 *         for x in [2/33,1),     -4<=m<=-1,  n=  0, f=x
 *
 *      In short:
 *      if x>0, let g: hg= ((hx + (0x200<<(-m)))>>(10-m))<<(10-m)
 *      then 1.f-1.g = x-g
 *      if x<0, let g': hg' =((ix-(0x200)<<(-m-1))>>(9-m))<<(9-m)
 *      (ix=hx&0x7fffffff)
 *      then 1.f-1.g = 2*(g'+x),
 *
 * (c). The final result is computed by
 *              (n*ln2_hi+_TBL_logl_hi[j]) +
 *                      ( (n*ln2_lo+_TBL_logl_lo[j]) + s*(A1+...) )
 *
 * Note.
 *      For ln2_hi and _TBL_logl_hi[j], we force their last 32 bit to be zero
 *      so that n*ln2_hi + _TBL_logl_hi[j] is exact. Here
 *      _TBL_logl_hi[j] + _TBL_logl_lo[j] match log(1+j*2**-6) to 194 bits
 *
 *
 * Special cases:
 *      log(x) is NaN with signal if x < 0 (including -INF) ;
 *      log(+INF) is +INF; log(0) is -INF with signal;
 *      log(NaN) is that NaN with no signal.
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following constants.
 * The decimal values may be used, provided that the compiler will convert
 * from decimal to binary accurately enough to produce the hexadecimal values
 * shown.

#pragma weak logl = __logl

/*
 * logl(x)
 * Table look-up algorithm
 * By K.C. Ng, March 6, 1989
 *
 * (a). For x in [31/33,33/31], using a special approximation:
 *      f = x - 1;
 *      s = f/(2.0+f);  ... here |s| <= 0.03125
 *      z = s*s;
 *      return f-s*(f-z*(B1+z*(B2+z*(B3+z*(B4+...+z*B9)...))));
 *
 * (b). Otherwise, normalize x = 2^n * 1.f.
 *      Use a 6-bit table look-up: find a 6 bit g that match f to 6.5 bits,
 *      then
 *          log(x) = n*ln2 + log(1.g) + log(1.f/1.g).
 *      Here the leading and trailing values of log(1.g) are obtained from
 *      a size-64 table.
 *      For log(1.f/1.g), let s = (1.f-1.g)/(1.f+1.g), then
 *          log(1.f/1.g) = log((1+s)/(1-s)) = 2s + 2/3 s^3 + 2/5 s^5 +...
 *      Note that |s|<2**-8=0.00390625. We use an odd s-polynomial
 *      approximation to compute log(1.f/1.g):
 *              s*(A1+s^2*(A2+s^2*(A3+s^2*(A4+s^2*(A5+s^2*(A6+s^2*A7))))))
 *      (Precision is 2**-136.91 bits, absolute error)
 *
 * (c). The final result is computed by
 *              (n*ln2_hi+_TBL_logl_hi[j]) +
 *                      ( (n*ln2_lo+_TBL_logl_lo[j]) + s*(A1+...) )
 *
 * Note.
 *      For ln2_hi and _TBL_logl_hi[j], we force their last 32 bit to be zero
```

```
 *      so that n*ln2_hi + _TBL_logl_hi[j] is exact. Here
 *      _TBL_logl_hi[j] + _TBL_logl_lo[j] match log(1+j*2**-6) to 194 bits
 *
 *
 * Special cases:
 *      log(x) is NaN with signal if x < 0 (including -INF) ;
 *      log(+INF) is +INF; log(0) is -INF with signal;
 *      log(NaN) is that NaN with no signal.
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following constants.
 * The decimal values may be used, provided that the compiler will convert
 * from decimal to binary accurately enough to produce the hexadecimal values
 * shown.
 */

 * sincosl(x)
 * Table look-up algorithm by K.C. Ng, November, 1989.
 *
 * kernel function:
 *      __k_sincosl     ... sin and cos function on [-pi/4,pi/4]
 *      __rem_pio2l     ... argument reduction routine
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C          -S            -C/S
 *          2         -S          -C             S/C
 *          3         -C           S            -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
 *      computer TRIG(x) returns trig(x) nearly rounded.
 */

 * sinl(x)
 * Table look-up algorithm by K.C. Ng, November, 1989.
 *
 * kernel function:
 *      __k_sinl                ... sin function on [-pi/4,pi/4]
 *      __k_cosl                ... cos function on [-pi/4,pi/4]
 *      __rem_pio2l     ... argument reduction routine
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C          -S            -C/S
 *          2         -S          -C             S/C
 *          3         -C           S            -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
 *      computer TRIG(x) returns trig(x) nearly rounded.
 */

/*
 * tanhl(x) returns the hyperbolic tangent of x
 *
 * Method :
 *      1. reduce x to non-negative:  tanhl(-x) = - tanhl(x).
 *      2.
 *        0      <  x <=  small    :  tanhl(x) := x
 *                                                -expm1l(-2x)
 *        small  <  x <=  1        :  tanhl(x) := --------------
 *                                                 expm1l(-2x) + 2
 *                                                       2
 *        1      <= x <= threshold :  tanhl(x) := 1 -  ---------------
 *                                                    expm1l(2x) + 2
 *     threshold <  x <= INF       :  tanhl(x) := 1.
 *
 * where
 *      single :        small = 1.e-5           threshold = 11.0
 *      double :        small = 1.e-10          threshold = 22.0
 *      quad   :        small = 1.e-20          threshold = 45.0
 *
 * Note: threshold was chosen so that
 *              fl(1.0+2/(expm1(2*threshold)+2)) == 1.
 *
 * Special cases:
 *      tanhl(NaN) is NaN;
 *      only tanhl(0.0)=0.0 is exact for finite argument.

 * tanl(x)
 * Table look-up algorithm by K.C. Ng, November, 1989.
 *
 * kernel function:
 *      __k_tanl        ... tangent function on [-pi/4,pi/4]
 *      __rem_pio2l     ... argument reduction routine
 *
 * Method.
 *      Let S and C denote the sin and cos respectively on [-PI/4, +PI/4].
 *      1. Assume the argument x is reduced to y1+y2 = x-k*pi/2 in
 *         [-pi/2 , +pi/2], and let n = k mod 4.
 *      2. Let S=S(y1+y2), C=C(y1+y2). Depending on n, we have
 *
 *          n        sin(x)      cos(x)        tan(x)
 *     ----------------------------------------------------------
 *          0          S           C             S/C
 *          1          C          -S            -C/S
 *          2         -S          -C             S/C
 *          3         -C           S            -C/S
 *     ----------------------------------------------------------
 *
 * Special cases:
 *      Let trig be any of sin, cos, or tan.
 *      trig(+-INF)  is NaN, with signals;
 *      trig(NaN)    is that NaN;
 *
 * Accuracy:
 *      computer TRIG(x) returns trig(x) nearly rounded.
 */

/* INDENT OFF */
/*
 * float atanf(float x);
 * Table look-up algorithm
 * By K.C. Ng, March 9, 1989
 *
 * Algorithm.
 *
 * The algorithm is based on atan(x)=atan(y)+atan((x-y)/(1+x*y)).
 * We use poly1(x) to approximate atan(x) for x in [0,1/8] with
 * error (relative)
 *      |(atan(x)-poly1(x))/x|<= 2^-115.94      long double
 *      |(atan(x)-poly1(x))/x|<= 2^-58.85       double
 *      |(atan(x)-poly1(x))/x|<= 2^-25.53       float
 * and use poly2(x) to approximate atan(x) for x in [0,1/65] with
 * error (absolute)
 *      |atan(x)-poly2(x)|<= 2^-122.15          long double
 *      |atan(x)-poly2(x)|<= 2^-64.79           double
 *      |atan(x)-poly2(x)|<= 2^-35.36           float
 * and use poly3(x) to approximate atan(x) for x in [1/8,7/16] with
 * error (relative, on for single precision)
 *      |(atan(x)-poly1(x))/x|<= 2^-25.53       float
 *
 * Here poly1-3 are odd polynomial with the following form:
 *              x + x^3*(a1+x^2*(a2+...))
 *
 * (0). Purge off Inf and NaN and 0
 * (1). Reduce x to positive by atan(x) = -atan(-x).
 * (2). For x <= 1/8, use
 *      (2.1) if x < 2^(-prec/2-2), atan(x) =  x  with inexact
```

```
 *      (2.2) Otherwise
 *              atan(x) = poly1(x)
 * (3). For x >= 8 then
 *      (3.1) if x >= 2^(prec+2),   atan(x) = atan(inf) - pio2lo
 *      (3.2) if x >= 2^(prec/3+2), atan(x) = atan(inf) - 1/x
 *      (3.3) if x >  65,           atan(x) = atan(inf) - poly2(1/x)
 *      (3.4) Otherwise,            atan(x) = atan(inf) - poly1(1/x)
 *
 * (4). Now x is in (0.125, 8)
 *      Find y that match x to 4.5 bit after binary (easy).
 *      If iy is the high word of y, then
 *              single : j = (iy - 0x3e000000) >> 19
 *              (single is modified to (iy-0x3f000000)>>19)
 *              double : j = (iy - 0x3fc00000) >> 16
 *              quad   : j = (iy - 0x3ffc0000) >> 12
 *
 *      Let s = (x-y)/(1+x*y). Then
 *      atan(x) = atan(y) + poly1(s)
 *              = _TBL_r_atan_hi[j] + (_TBL_r_atan_lo[j] + poly2(s) )
 *
 *      Note. |s| <= 1.5384615385e-02 = 1/65. Maxium occurs at x = 1.03125
 *
 */

/* INDENT OFF */
/*
 * float expf(float x);
 * Code by K.C. Ng for SUN 5.0 libmopt
 * 11/5/99
 * Method :
 *      1. For |x| >= 2^7, either underflow/overflow.
 *         More precisely:
 *              x > 88.722839355...(0x42B17218) => overflow;
 *              x < -103.97207642..(0xc2CFF1B4) => underflow.
 *      2. For |x| <  2^-6, use polynomail
 *              exp(x) = 1 + x + p1*x^2 + p2*x^3
 *      3. Otherwise, write |x|=(1+r)*2^n, where 0<=r<1.
 *         Let t = 2^n * (1+r) .... x > 0;
 *             t = 2^n * (1-r) .... x < 0. (x= -2**(n+1)+t)
 *         Since -6 <= n <= 6, we may break t into
 *         six 6-bits chunks:
 *                    -5     -11     -17     -23     -29
 *         t=j *2+j *2  +j *2   +j *2   +j *2   +j *2
 *            1    2      3       4       5       6
 *
 *         where 0 <= j  < 64 for i = 1,...,6.
 *                      i
 *         Note that since t has only 24 significant bits,
 *         either j  or j  must be 0.
 *                1     6
 *                                            7-6i
 *         One may define j  by   (int) ( t * 2     ) mod 64
 *                        i
 *         mathematically. In actual implementation, they can
 *         be obtained by manipulating the exponent and
```

```
 *         mantissa bits as follow:
 *              Let ix = (HEX(x)&0x007fffff)|0x00800000.
 *              If n>=0, let ix=ix<<n, then j =0 and
 *                                           6
 *                  j  = ix>>(30-6i)) mod 64  ...i=1,...,5
 *                   i
 *              Otherwise, let ix=ix<<(j+6), then j = 0 and
 *                                                 1
 *                  j  = ix>>(36-6i)) mod 64  ...i=2,...,6
 *                   i
 *
 *      4. Compute exp(t) by table look-up method.
 *         Precompute ET[k] = exp(j*2^(7-6i)), k=j+64*(6-i).
 *         Then
 *         exp(t) = ET[j +320]*ET[j +256]*ET[j +192]*
 *                      1          2          3
 *
 *                  ET[j +128]*ET[j +64]*ET[j ]
 *                      4          5         6
 *
 *                                  n+1
 *      5. If x < 0, return exp(-2   )* exp(t). Note that
 *         -6 <= n <= 6. Let k = n - 6, then we can
 *         precompute
 *                         k-5          n+1
 *         EN[k] = exp(-2   ) = exp(-2   ) for k=0,1,...,12.
 *
 *
 * Special cases:
 *      exp(INF) is INF, exp(NaN) is NaN;
 *      exp(-INF) = 0;
 *      for finite argument, only exp(0) = 1 is exact.
 *
 * Accuracy:
 *      All calculations are done in double precision except for
 *      the case |x| < 2^-6.  When |x| < 2^-6, the error is less
 *      than 0.55 ulp.  When |x| >= 2^-6 and the result is normal,
 *      the error is less than 0.51 ulp.  When FDTOS_TRAPS_... is
 *      defined and the result is subnormal, the error can be as
 *      large as 0.75 ulp.

#pragma weak logf = __logf

/*
 * Algorithm:
 *
 * Let y = x rounded to six significant bits.  Then for any choice
 * of e and z such that y = 2^e z, we have
 *
 * log(x) = e log(2) + log(z) + log(1+(x-y)/y)
 *
 * Note that (x-y)/y = (x'-y')/y' for any scaled x' = sx, y' = sy;
 * in particular, we can take s to be the power of two that makes
 * ulp(x') = 1.
 *
 * From a table, obtain l = log(z) and r = 1/y'.  For |s| <= 2^-6,
 * approximate log(1+s) by a polynomial p(s) where p(s) := s+s*s*
 * (K1+s*(K2+s*K3)).  Then we compute the expression above as
 * e*ln2 + l + p(r*(x'-y')) all evaluated in double precision.
 *
 * When x is subnormal, we first scale it to the normal range,
 * adjusting e accordingly.
 *
 * Accuracy:
 *
 * The largest error is less than 0.6 ulps.
 */

/* INDENT OFF */
/*
 * dcomplex cacos(dcomplex z);
 *
 * Alogrithm
 * (based on T.E.Hull, Thomas F. Fairgrieve and Ping Tak Peter Tang's
 * paper "Implementing the Complex Arcsine and Arccosine Functins Using
 * Exception Handling", ACM TOMS, Vol 23, pp 299-335)
 *
 * The principal value of complex inverse cosine function cacos(z),
 * where z = x+iy, can be defined by
 *
 *      cacos(z) = acos(B) - i sign(y) log (A + sqrt(A*A-1)),
 *
 * where the log function is the natural log, and
 *                  ____________                ____________
 *       1    /     2    2      1    /     2    2
 *  A = ---  / (x+1)  + y   +  ---  / (x-1)  + y
 *       2 \/                   2 \/
 *                  ____________                ____________
 *       1    /     2    2      1    /     2    2
 *  B = ---  / (x+1)  + y   -  ---  / (x-1)  + y   .
 *       2 \/                   2 \/
 *
 * The Branch cuts are on the real line from -inf to -1 and from 1 to inf.
 * The real and imaginary parts are based on Abramowitz and Stegun
 * [Handbook of Mathematic Functions, 1972].  The sign of the imaginary
 * part is chosen to be the generally considered the principal value of
 * this function.
 *
```

```
 * Notes:1. A is the average of the distances from z to the points (1,0)
 *          and (-1,0) in the complex z-plane, and in particular A>=1.
 *       2. B is in [-1,1], and A*B = x
 *
 * Basic relations
 *    cacos(conj(z)) = conj(cacos(z))
 *    cacos(-z)      = pi   - cacos(z)
 *    cacos( z)      = pi/2 - casin(z)
 *
 * Special cases (conform to ISO/IEC 9899:1999(E)):
 *    cacos(+-0  + i y  ) = pi/2 - i y for y is +-0, +-inf, NaN
 *    cacos( x   + i inf) = pi/2 - i inf for all x
 *    cacos( x   + i NaN) = NaN  + i NaN with invalid for non-zero finite x
 *    cacos(-inf + i y  ) = pi   - i inf for finite +y
 *    cacos( inf + i y  ) = 0    - i inf for finite +y
 *    cacos(-inf + i inf) = 3pi/4- i inf
 *    cacos( inf + i inf) = pi/4 - i inf
 *    cacos(+-inf+ i NaN) = NaN  - i inf (sign of imaginary is unspecified)
 *    cacos(NaN  + i y  ) = NaN  + i NaN with invalid for finite y
 *    cacos(NaN  + i inf) = NaN  - i inf
 *    cacos(NaN  + i NaN) = NaN  + i NaN
 *
 * Special Regions (better formula for accuracy and for avoiding spurious
 * overflow or underflow) (all x and y are assumed nonnegative):
 *  case 1: y = 0
 *  case 2: tiny y relative to x-1: y <= ulp(0.5)*|x-1|
 *  case 3: tiny y: y < 4 sqrt(u), where u = minimum normal number
 *  case 4: huge y relative to x+1: y >= (1+x)/ulp(0.5)
 *  case 5: huge x and y: x and y >= sqrt(M)/8, where M = maximum normal number
 *  case 6: tiny x: x < 4 sqrt(u)
 *  --------
 *  case        1 & 2. y=0 or y/|x-1| is tiny. We have
 *                  ____________                ____________
 *            /     2    2              /       y    2
 *           / (x+-1)  + y   =  |x+-1| / 1 + (------)
 *         \/                         \/       |x+-1|
 *
 *                                        1     y    2
 *                            ~  |x+-1| ( 1 + --- (------)  )
 *                                        2   |x+-1|
 *
 *                                     2
 *                                    y
 *                            = |x+-1| + --------.
 *                                       2|x+-1|
 *
 *      Consequently, it is not difficult to see that
 *                                    2
 *                                   y
 *                    [ 1 + ------------ ,     if x < 1,
 *                    [      2(1+x)(1-x)
 *                    [
 *                    [
 *                    [ x,                    if x = 1 (y = 0),
 *                    [
 *              A ~=  [            2
 *                    [         x * y
 *                    [ x + ------------ ~ x,  if x > 1
 *                    [      2(x+1)(x-1)
 *
 *      and hence
 *                                 _____                              2
 *                               / 2                    y            y
 *               A + \/ A  - 1  ~  1 + ---------------- + -----------, if x < 1,
 *                                     sqrt((x+1)(1-x))   2(x+1)(1-x)
 *
```

```
 *
 *                              ~  x + sqrt((x-1)*(x+1)),            if x >= 1.
 *
 *                                      2
 *                                     y
 *                           [ x(1 - -----------) ~ x,  if x < 1,
 *                           [       2(1+x)(1-x)
 *              B = x/A  ~   [
 *                           [ 1,                       if x = 1,
 *                           [
 *                           [           2
 *                           [          y
 *                           [ 1 - ------------ ,       if x > 1,
 *                           [      2(x+1)(x-1)
 *      Thus
 *                             [ acos(x) - i y/sqrt((x-1)*(x+1)),     if x < 1,
 *                             [
 *              cacos(x+i*y)~  [ 0 - i 0,                             if x = 1,
 *                             [
 *                             [ y/sqrt(x*x-1) - i log(x+sqrt(x*x-1)), if x > 1.
 *
 *      Note: y/sqrt(x*x-1) ~ y/x when x >= 2**26.
 *  case 3. y < 4 sqrt(u), where u = minimum normal x.
 *      After case 1 and 2, this will only occurs when x=1. When x=1, we have
 *         A = (sqrt(4+y*y)+y)/2 ~ 1 + y/2 + y^2/8 + ...
 *      and
 *         B = 1/A = 1 - y/2 + y^2/8 + ...
 *      Since
 *         cos(sqrt(y)) ~ 1 - y/2 + ...
 *      we have, for the real part,
 *         acos(B) ~ acos(1 - y/2) ~ sqrt(y)
 *      For the imaginary part,
 *         log(A+sqrt(A*A-1)) ~ log(1+y/2+sqrt(2*y/2))
 *                            = log(1+y/2+sqrt(y))
 *                            = (y/2+sqrt(y)) - (y/2+sqrt(y))^2/2 + ...
 *                            ~ sqrt(y) - y*(sqrt(y)+y/2)/2
 *                            ~ sqrt(y)
 *
 *  case 4. y >= (x+1)/ulp(0.5). In this case, A ~ y and B ~ x/y. Thus
 *         real part = acos(B) ~ pi/2
 *      and
 *         imag part = log(y+sqrt(y*y-one))
 *
 *  case 5. Both x and y are large: x and y > sqrt(M)/8, where M = maximum x
 *      In this case,
 *         A ~ sqrt(x*x+y*y)
 *         B ~ x/sqrt(x*x+y*y).
 *      Thus
 *         real part = acos(B) = atan(y/x),
 *         imag part = log(A+sqrt(A*A-1)) ~ log(2A)
 *                   = log(2) + 0.5*log(x*x+y*y)
 *                   = log(2) + log(y) + 0.5*log(1+(x/y)^2)
 *
 *  case 6. x < 4 sqrt(u). In this case, we have
 *         A ~ sqrt(1+y*y), B = x/sqrt(1+y*y).
 *      Since B is tiny, we have
 *          real part = acos(B) ~ pi/2
 *          imag part = log(A+sqrt(A*A-1)) = log (A+sqrt(y*y))
 *                    = log(y+sqrt(1+y*y))
 *                    = 0.5*log(y^2+2ysqrt(1+y^2)+1+y^2)
 *                    = 0.5*log(1+2y(y+sqrt(1+y^2)));
 *                    = 0.5*log1p(2y(y+A));
 *
 *      cacos(z) = acos(B) - i sign(y) log (A + sqrt(A*A-1)),

/* INDENT OFF */
/*
 * dcomplex casin(dcomplex z);
 *
 * Alogrithm
 * (based on T.E.Hull, Thomas F. Fairgrieve and Ping Tak Peter Tang's
 * paper "Implementing the Complex Arcsine and Arccosine Functins Using
 * Exception Handling", ACM TOMS, Vol 23, pp 299-335)
 *
 * The principal value of complex inverse sine function casin(z),
 * where z = x+iy, can be defined by
 *
 *      casin(z) = asin(B) + i sign(y) log (A + sqrt(A*A-1)),
 *
 * where the log function is the natural log, and
 *                    _____________           _____________
 *       1    /     2    2      1    /     2    2
 *  A = ---  / (x+1)  + y   +  ---  / (x-1)  + y
 *       2 \/                   2 \/
 *                    _____________           _____________
 *       1    /     2    2      1    /     2    2
 *  B = ---  / (x+1)  + y   -  ---  / (x-1)  + y   .
 *       2 \/                   2 \/
 *
 * The Branch cuts are on the real line from -inf to -1 and from 1 to inf.
 * The real and imaginary parts are based on Abramowitz and Stegun
 * [Handbook of Mathematic Functions, 1972].  The sign of the imaginary
 * part is chosen to be the generally considered the principal value of
 * this function.
 *
```

```
 * Notes:1. A is the average of the distances from z to the points (1,0)
 *          and (-1,0) in the complex z-plane, and in particular A>=1.
 *       2. B is in [-1,1], and A*B = x.
 *
 * Special notes: if casin( x, y) = ( u, v), then
 *                  casin(-x, y) = (-u, v),
 *                  casin( x,-y) = ( u,-v),
 *    in general, we have casin(conj(z))     =  conj(casin(z))
 *                        casin(-z)          = -casin(z)
 *                        casin(z)           =  pi/2 - cacos(z)
 *
 * EXCEPTION CASES (conform to ISO/IEC 9899:1999(E)):
 *    casin( 0 + i 0   ) =  0    + i 0
 *    casin( 0 + i NaN ) =  0    + i NaN
 *    casin( x + i inf ) =  0    + i inf for finite x
 *    casin( x + i NaN ) =  NaN  + i NaN with invalid for finite x!=0
 *    casin(inf + iy   ) =  pi/2 + i inf finite y
 *    casin(inf + i inf) =  pi/4 + i inf
 *    casin(inf + i NaN) =  NaN  + i inf
 *    casin(NaN + i y  ) =  NaN  + i NaN for finite y
 *    casin(NaN + i inf) =  NaN  + i inf
 *    casin(NaN + i NaN) =  NaN  + i NaN
 *
 * Special Regions (better formula for accuracy and for avoiding spurious
 * overflow or underflow) (all x and y are assumed nonnegative):
 *  case 1: y = 0
 *  case 2: tiny y relative to x-1: y <= ulp(0.5)*|x-1|
 *  case 3: tiny y: y < 4 sqrt(u), where u = minimum normal number
 *  case 4: huge y relative to x+1: y >= (1+x)/ulp(0.5)
 *  case 5: huge x and y: x and y >= sqrt(M)/8, where M = maximum normal number
 *  case 6: tiny x: x < 4 sqrt(u)
 *  --------
 *  case        1 & 2. y=0 or y/|x-1| is tiny. We have
 *                    _____________                 _____________
 *              /     2    2                 /       y    2
 *           / (x+-1)  + y   =  |x+-1| / 1 + (------)
 *         \/                          \/       |x+-1|
 *
 *                                          1     y   2
 *                            ~  |x+-1| ( 1 + --- (------)  )
 *                                          2   |x+-1|
 *
 *                                        2
 *                                       y
 *                            =  |x+-1| + --------.
 *                                       2|x+-1|
 *
 *      Consequently, it is not difficult to see that
 *                                    2
 *                                   y
 *                    [ 1 + ------------ ,  if x < 1,
 *                    [      2(1+x)(1-x)
 *                    [
 *                    [
 *                    [ x,                 if x = 1 (y = 0),
 *                    [
 *              A ~=  [             2
 *                    [        x * y
 *                    [ x + ------------ ,  if x > 1
 *                    [      2(1+x)(x-1)
 *
 *      and hence
 *                                 _____                                 2
 *                              / 2                    y               y
 *               A + \/ A  - 1  ~  1 + ---------------- + -----------, if x < 1,
 *                                     sqrt((x+1)(1-x))   2(x+1)(1-x)
 *
```

```
 *
 *                             ~  x + sqrt((x-1)*(x+1)),             if x >= 1.
 *
 *                                      2
 *                                     y
 *                           [ x(1 - ------------), if x < 1,
 *                           [       2(1+x)(1-x)
 *              B = x/A  ~   [
 *                           [ 1,                  if x = 1,
 *                           [
 *                           [          2
 *                           [         y
 *                           [ 1 - ------------ ,   if x > 1,
 *                           [      2(1+x)(1-x)
 *      Thus
 *                             [ asin(x) + i y/sqrt((x-1)*(x+1)), if x <  1
 *              casin(x+i*y)=[
 *                             [ pi/2    + i log(x+sqrt(x*x-1)),  if x >= 1
 *
 *  case 3. y < 4 sqrt(u), where u = minimum normal x.
 *      After case 1 and 2, this will only occurs when x=1. When x=1, we have
 *         A = (sqrt(4+y*y)+y)/2 ~ 1 + y/2 + y^2/8 + ...
 *      and
 *         B = 1/A = 1 - y/2 + y^2/8 + ...
 *      Since
 *         asin(x) = pi/2-2*asin(sqrt((1-x)/2))
 *         asin(x) = x + x^3/6 + x^5*3/40 + x^7*15/336 + ...
 *      we have, for the real part asin(B),
 *         asin(1-y/2) ~ pi/2 - 2 asin(sqrt(y/4))
 *                     ~ pi/2 - sqrt(y)
 *      For the imaginary part,
 *         log(A+sqrt(A*A-1)) ~ log(1+y/2+sqrt(2*y/2))
 *                            = log(1+y/2+sqrt(y))
 *                            = (y/2+sqrt(y)) - (y/2+sqrt(y))^2/2 + ...
 *                            ~ sqrt(y) - y*(sqrt(y)+y/2)/2
 *                            ~ sqrt(y)
 *
 *  case 4. y >= (x+1)ulp(0.5). In this case, A ~ y and B ~ x/y. Thus
 *        real part = asin(B) ~ x/y (be careful, x/y may underflow)
 *      and
 *         imag part = log(y+sqrt(y*y-one))
 *
 *
 *  case 5. Both x and y are large: x and y > sqrt(M)/8, where M = maximum x
 *      In this case,
 *         A ~ sqrt(x*x+y*y)
 *         B ~ x/sqrt(x*x+y*y).
 *      Thus
 *         real part = asin(B) = atan(x/y),
 *         imag part = log(A+sqrt(A*A-1)) ~ log(2A)
 *                   = log(2) + 0.5*log(x*x+y*y)
 *                   = log(2) + log(y) + 0.5*log(1+(x/y)^2)
 *
 *  case 6. x < 4 sqrt(u). In this case, we have
 *          A ~ sqrt(1+y*y), B = x/sqrt(1+y*y).
 *      Since B is tiny, we have
 *          real part = asin(B) ~ B = x/sqrt(1+y*y)
 *          imag part = log(A+sqrt(A*A-1)) = log (A+sqrt(y*y))
 *                    = log(y+sqrt(1+y*y))
 *                    = 0.5*log(y^2+2ysqrt(1+y^2)+1+y^2)
 *                    = 0.5*log(1+2y(y+sqrt(1+y^2)));
 *                    = 0.5*log1p(2y(y+A));
 *
 *      casin(z) = asin(B) + i sign(y) log (A + sqrt(A*A-1)),
