 *
 * Atan(z) return A + Bi where,
 *              1
 *      A = --- * atan2(2x, 1-x*x-y*y)
 *              2
 *
 *              1      [ x*x + (y+1)*(y+1) ]   1              4y
 *       B = --- log [ ----------------- ] = - log (1+ -----------------)
 *              4      [ x*x + (y-1)*(y-1) ]   4         x*x + (y-1)*(y-1)
 *
 *                   2    16  3                        y
 *         = t - 2t   + -- t  - ..., where t = -----------------
 *                      3                      x*x + (y-1)*(y-1)
 * Proof:
 * Let w = atan(z=x+yi) = A + B i. Then tan(w) = z.
 * Since sin(w) = (exp(iw)-exp(-iw))/(2i), cos(w)=(exp(iw)+exp(-iw))/(2),
 * Let p = exp(iw), then z = tan(w) = ((p-1/p)/(p+1/p))/i, or
 * iz = (p*p-1)/(p*p+1), or, after simplification,
 *      p*p = (1+iz)/(1-iz)                                  ... (1)
 * LHS of (1) = exp(2iw) = exp(2i(A+Bi)) = exp(-2B)*exp(2iA)
 *            = exp(-2B)*(cos(2A)+i*sin(2A))                 ... (2)
 *              1-y+ix   (1-y+ix)*(1+y+ix)   1-x*x-y*y + 2xi
 * RHS of (1) = ------ = ---------------- = -------------- ... (3)
 *              1+y-ix    (1+y)**2 + x**2    (1+y)**2 + x**2
 *
 * Comparing the real and imaginary parts of (2) and (3), we have:
```

```
 *      cos(2A) : 1-x*x-y*y = sin(2A) : 2x
 * and hence
 *      tan(2A) = 2x/(1-x*x-y*y), or
 *      A = 0.5 * atan2(2x, 1-x*x-y*y)                    ... (4)
 *
 * For the imaginary part B, Note that |p*p| = exp(-2B), and
 *      |1+iz|   |i-z|   hypot(x,(y-1))
 *       |---| = |---| = --------------
 *      |1-iz|   |i+z|   hypot(x,(y+1))
 * Thus
 *                 x*x + (y+1)*(y+1)
 *      exp(4B) = -----------------, or
 *                 x*x + (y-1)*(y-1)
 *
 *           1     [x^2+(y+1)^2]   1             4y
 *       B =  - log [-----------] = - log(1+ -------------)  ... (5)
 *           4     [x^2+(y-1)^2]   4         x^2+(y-1)^2
 *
 * QED.
 *
 * Note that: if catan( x, y) = ( u, v), then
 *              catan(-x, y) = (-u, v)
 *              catan( x,-y) = ( u,-v)
 *
 * Also,   catan(x,y) = -i*catanh(-y,x), or
 *        catanh(x,y) =  i*catan(-y,x)
 * So, if catanh(y,x) = (v,u), then catan(x,y) = -i*(-v,u) = (u,v), i.e.,
 *         catan(x,y) = (u,v)

 *            e   +  e        e  (cos(y)+i*sin(y)) + e  (cos(-y)+i*sin(-y))
 * cosh z = -------------- =  ----------------------------------------
 *                2                          2
 *                    x    -x              x    -x
 *           cos(y) ( e  + e  )  + i*sin(y) (e  - e  )
 *       = ----------------------------------------
 *                           2
 *
 *       =  cos(y) cosh(x)  + i sin(y) sinh(x)
 *
 * Implementation Note
 * -------------------
 *
 *            |x|    -|x|   |x|        -2|x|       -2|x|    -P-4
 * Note that  e   +- e    = e   ( 1 +- e     ). If e      < 2     , where
 *
 * P stands for the number of significant bits of the machine precision,
 *                                    |x|
 * then the result will be rounded to e   . Therefore, we have
 *
 *                z
 *               e
 *     cosh z = -----  if |x| >= (P/2 + 2)*ln2
 *               2
 *

/* INDENT OFF */
/*
 * dcomplex cpow(dcomplex z);
 *
 * z**w analytically equivalent to
 *
 * cpow(z,w) = cexp(w clog(z))
 *
 * Let z = x+iy, w = u+iv.
 * Since
 *                                  _________
 *                                 / 2    2          -1   y
 *     log(x+iy) = log(\/ x  + y    ) + i tan   (---)
 *                                              x
 *
 *                    1       2    2         -1   y
 *                = --- log(x  + y ) + i tan   (---)
 *                    2                      x
 *                         u       2    2         -1  y
 * (u+iv)* log(x+iy) =  --- log(x  + y ) - v tan  (---)  +          (1)
 *                         2                      x
 *
 *                               v       2    2         -1  y
 *                        i * [ --- log(x  + y ) + u tan  (---) ]      (2)
 *                               2                      x
 *
 *                    = r + i q
 *
 * Therefore,
```

```
 *      w     r+iq    r
 *     z  =  e     = e  (cos(q)+i*sin(q))
 *                                  _____
 *                                 / 2   2
 *       r                        \/ x + y     -v*atan2(y,x)
 * Here e  can be expressed as:  u          * e
 *
 * Special cases (in the order of appearance):
 *      1.  (anything) ** 0  is 1
 *      2.  (anything) ** 1  is itself
 *      3.  When v = 0, y = 0:
 *            If x is finite and negative, and u is finite, then
 *               x ** u = exp(u*pi i) * pow(|x|, u);
 *            otherwise,
 *               x ** u = pow(x, u);
 *      4.  When v = 0, x = 0 or |x| = |y| or x is inf or y is inf:
 *               (x + y i) ** u = r * exp(q i)
 *           where
 *               r = hypot(x,y) ** u
 *               q = u * atan2pi(y, x)
 *
 *      5.  otherwise, z**w is NAN if any x, y, u, v is a Nan or inf
 *
 *      Note: many results of special cases are obtained in terms of
 *      polar coordinate. In the conversion from polar to rectangle:
 *                   r exp(q i) = r * cos(q) + r * sin(q) i,
 *      we regard r * 0 is 0 except when r is a NaN.

#pragma weak csqrt = __csqrt

/* INDENT OFF */
/*
 * dcomplex csqrt(dcomplex z);
 *                                          2    2    2
 * Let w=r+i*s = sqrt(x+iy). Then (r + i s)  = r  - s  + i 2sr = x + i y.
 *
 * Hence x = r*r-s*s, y = 2sr.
 *
 * Note that x*x+y*y = (s*s+r*r)**2. Thus, we have
 *                                    _______
 *           2    2     / 2    2
 *      (1) r  + s  = \/ x  + y  ,
 *
 *           2    2
 *       (2) r  - s  = x
 *
 *      (3) 2sr = y.
 *
 * Perform (1)-(2) and (1)+(2), we obtain
 *
 *             2
 *      (4) 2 r   = hypot(x,y)+x,
 *
 *             2
 *       (5) 2*s   = hypot(x,y)-x
 *                        _______
 *                       / 2    2
 * where hypot(x,y) = \/ x  + y  .
 *
```

```
 * In order to avoid numerical cancellation, we use formula (4) for
 * positive x, and (5) for negative x. The other component is then
 * computed by formula (3).
 *
 *
 * ALGORITHM
 * -----------------
 *
 * (assume x and y are of medium size, i.e., no over/underflow in squaring)
 *
 * If x >=0 then
 *                                  _______
 *                                 /  2    2
 *             2     \/  x  + y    +  x                y
 *            r =   ---------------------,      s = -------;    (6)
 *                                 2                    2 r
 *
 * (note that we choose sign(s) = sign(y) to force r >=0).
 * Otherwise,
 *                                  _______
 *                                 /  2    2
 *             2     \/  x  + y    -  x                y
 *            s =   ---------------------,      r = -------;    (7)
 *                                 2                    2 s
 *
 * EXCEPTION:
 *
 * One may use the polar coordinate of a complex number to justify the
 * following exception cases:
 *
 * EXCEPTION CASES (conform to ISO/IEC 9899:1999(E)):
 *    csqrt(+-0+ i 0   ) =  0    + i 0
 *    csqrt( x + i inf ) =  inf  + i inf for all x (including NaN)
 *    csqrt( x + i NaN ) =  NaN  + i NaN with invalid for finite x
 *    csqrt(-inf+ iy   ) =  0    + i inf for finite positive-signed y
 *    csqrt(+inf+ iy   ) =  inf  + i 0   for finite positive-signed y
 *    csqrt(-inf+ i NaN) =  NaN  +-i inf
 *    csqrt(+inf+ i NaN) =  inf  + i NaN
 *    csqrt(NaN + i y  ) =  NaN  + i NaN for finite y
 *    csqrt(NaN + i NaN) =  NaN  + i NaN

/*
 * double __k_atan2(double y, double x, double *e)
 *
 * Compute atan2 with error terms.
 *
 * Important formula:
 *                  3      5
 *                 x      x
 * atan(x) = x - ----- + ----- - ...    (for x <= 1)
 *                 3      5
 *
 *          pi     1     1
 *        = --- - --- + --- - ...      (for x > 1)
 *                    3
 *           2     x    3x
 *
 * Arg(x + y i) = sign(y) * atan2(|y|, x)
 *              = sign(y) * atan(|y|/x)          (for x > 0)
 *                sign(y) * (PI - atan(|y|/|x|))  (for x < 0)
 * Thus if x >> y (IEEE double: EXP(x) - EXP(y) >= 60):
 *      1. (x > 0): atan2(y,x) ~ y/x
 *      2. (x < 0): atan2(y,x) ~ sign(y) (PI - |y/x|))
 * Otherwise if x << y:
 *      atan2(y,x) ~ sign(y)*PI/2 - x/y
 *

/*
 * mx_atan(x,err)
```

```
 * Table look-up algorithm
 * By K.C. Ng, March 9, 1989
 *
 * Algorithm.
 *
 * The algorithm is based on atan(x)=atan(y)+atan((x-y)/(1+x*y)).
 * We use poly1(x) to approximate atan(x) for x in [0,1/8] with
 * error (relative)
 *      |(atan(x)-poly1(x))/x|<= 2^-83.41
 *
 * and use poly2(x) to approximate atan(x) for x in [0,1/65] with
 * error
 *      |atan(x)-poly2(x)|<= 2^-86.8
 *
 * Here poly1 and poly2 are odd polynomial with the following form:
 *              x + x^3*(a1+x^2*(a2+...))
 *
 * (0). Purge off Inf and NaN and 0
 * (1). Reduce x to positive by atan(x) = -atan(-x).
 * (2). For x <= 1/8, use
 *      (2.1) if x < 2^(-prec/2), atan(x) =  x  with inexact flag raised
 *      (2.2) Otherwise
 *              atan(x) = poly1(x)
 * (3). For x >= 8 then (prec = 78)
 *      (3.1) if x >= 2^prec,     atan(x) = atan(inf) - pio2lo
 *      (3.2) if x >= 2^(prec/3), atan(x) = atan(inf) - 1/x
 *      (3.3) if x >  65,         atan(x) = atan(inf) - poly2(1/x)
 *      (3.4) Otherwise,          atan(x) = atan(inf) - poly1(1/x)
 *
 * (4). Now x is in (0.125, 8)
 *      Find y that match x to 4.5 bit after binary (easy).
 *      If iy is the high word of y, then
 *              single : j = (iy - 0x3e000000) >> 19
 *              double : j = (iy - 0x3fc00000) >> 16
 *              quad   : j = (iy - 0x3ffc0000) >> 12
 *
 *      Let s = (x-y)/(1+x*y). Then
 *      atan(x) = atan(y) + poly1(s)
 *              = _TBL_atan_hi[j] + (_TBL_atan_lo[j] + poly2(s) )
 *
 *      Note. |s| <= 1.5384615385e-02 = 1/65. Maxium occurs at x = 1.03125
 *

/*
 * long double __k_atan2l(long double y, long double x, long double *e)
 *
 * Compute atan2l with error terms.
 *
 * Important formula:
 *                  3       5
 *                 x       x
 * atan(x) = x - ----- + ----- - ...    (for x <= 1)
 *                 3       5
 *
 *          pi     1     1
 *        = --- - --- + --- - ...      (for x > 1)
 *                  3
 *           2     x    3x
 *
 * Arg(x + y i) = sign(y) * atan2(|y|, x)
 *              = sign(y) * atan(|y|/x)          (for x > 0)
 *                sign(y) * (PI - atan(|y|/|x|))  (for x < 0)
 * Thus if x >> y (IEEE double: EXP(x) - EXP(y) >= 60):
 *      1. (x > 0): atan2(y,x) ~ y/x
 *      2. (x < 0): atan2(y,x) ~ sign(y) (PI - |y/x|))
 * Otherwise if x << y:
 *      atan2(y,x) ~ sign(y)*PI/2 - x/y
```

431 /*
432  * mx_atanl(x, err)
433  * Table look-up algorithm
434  * By K.C. Ng, March 9, 1989
435  *
436  * Algorithm.
437  *
438  * The algorithm is based on atan(x)=atan(y)+atan((x-y)/(1+x*y)).
439  * We use poly1(x) to approximate atan(x) for x in [0,1/8] with
440  * error (relative)
441  *      |(atan(x)-poly1(x))/x|<= 2^-140
442  *
443  * and use poly2(x) to approximate atan(x) for x in [0,1/65] with
444  * error
445  *      |atan(x)-poly2(x)|<= 2^-143.7
446  *
447  * Here poly1 and poly2 are odd polynomial with the following form:
448  *              x + x^3*(a1+x^2*(a2+...))
449  *
450  * (0). Purge off Inf and NaN and 0
451  * (1). Reduce x to positive by atan(x) = -atan(-x).
452  * (2). For x <= 1/8, use
453  *      (2.1) if x < 2^(-prec/2), atan(x) =  x  with inexact flag raised
454  *      (2.2) Otherwise
455  *              atan(x) = poly1(x)
456  * (3). For x >= 8 then (prec = 78)
457  *
```

```
458  *      (3.1) if x >= 2^prec,     atan(x) = atan(inf) - pio2_lo
459  *      (3.2) if x >= 2^(prec/3), atan(x) = atan(inf) - 1/x
460  *      (3.3) if x >  65,         atan(x) = atan(inf) - poly2(1/x)
461  *      (3.4) Otherwise,          atan(x) = atan(inf) - poly1(1/x)
462  *
463  * (4). Now x is in (0.125, 8)
464  *      Find y that match x to 4.5 bit after binary (easy).
465  *      If iy is the high word of y, then
466  *              single : j = (iy - 0x3e000000) >> 19
467  *              double : j = (iy - 0x3fc00000) >> 16
468  *              quad   : j = (iy - 0x3ffc0000) >> 12
469  *
470  *      Let s = (x-y)/(1+x*y). Then
471  *      atan(x) = atan(y) + poly1(s)
472  *              = _TBL_atan_hi[j] + (_TBL_atan_lo[j] + poly2(s) )
473  *
474  *      Note. |s| <= 1.5384615385e-02 = 1/65. Maxium occurs at x = 1.03125
475  *
476  */

/*
 * double __k_cexp(double x, int *n);
 * Returns the exponential of x in the form of 2**n * y, y=__k_cexp(x,&n).
 *
 * Method
 *   1. Argument reduction:
 *      Reduce x to an r so that |r| <= 0.5*ln2 ~ 0.34658.
 *      Given x, find r and integer k such that
 *
 *               x = k*ln2 + r,  |r| <= 0.5*ln2.
 *
 *      Here r will be represented as r = hi-lo for better
 *      accuracy.
 *
 *   2. Approximation of exp(r) by a special rational function on
 *      the interval [0,0.34658]:
 *      Write
 *          R(r**2) = r*(exp(r)+1)/(exp(r)-1) = 2 + r*r/6 - r**4/360 + ...
 *      We use a special Remez algorithm on [0,0.34658] to generate
 *      a polynomial of degree 5 to approximate R. The maximum error
 *      of this polynomial approximation is bounded by 2**-59. In
 *      other words,
 *          R(z) ~ 2.0 + P1*z + P2*z**2 + P3*z**3 + P4*z**4 + P5*z**5
 *      (where z=r*r, and the values of P1 to P5 are listed below)
 *      and
 *          |                    5          |     -59
 *          | 2.0+P1*z+...+P5*z   -  R(z) | <= 2
 *          |                               |
 *      The computation of exp(r) thus becomes
 *                             2*r
```

```
 *              exp(r) = 1 + -------
 *                             R - r
 *                                 r*R1(r)
 *                       = 1 + r + ----------- (for better accuracy)
 *                                 2 - R1(r)
 *      where
 *                                  2       4            10
 *              R1(r) = r - (P1*r  + P2*r  + ... + P5*r   ).
 *
 *   3. Return n = k and __k_cexp = exp(r).
 *
 * Special cases:
 *      exp(INF) is INF, exp(NaN) is NaN;
 *      exp(-INF) is 0, and
 *      for finite argument, only exp(0)=1 is exact.
 *
 * Range and Accuracy:
 *      When |x| is really big, say |x| > 50000, the accuracy
 *      is not important because the ultimate result will over or under
 *      flow. So we will simply replace n = 50000 and r = 0.0. For
 *      moderate size x, according to an error analysis, the error is
 *      always less than 1 ulp (unit in the last place).
 *
 * Constants:
 * The hexadecimal values are the intended ones for the following
 * constants. The decimal values may be used, provided that the
 * compiler will convert from decimal to binary accurately enough
 * to produce the hexadecimal values shown.

 *
 * Note 1. For IEEE double precision,  a seven degree odd polynomial
 *              2s + P1*(2s)^3 + P2*(2s)^5 + P3*(2s)^7
 *         is generated by a special remez algorithm to
 *         approx log((1+s)/(1-s)) accurte to 72 bits.
 * Note 2. 2s can be computed accurately as s2h+s2t by
 *         r = 2/((zh+zt)+2(1+zk))
 *         s2 = r*(zh+zt)
 *         s2h = s2 rounded to float;  v = 0.5*s2h;
 *         s2t = r*((((zh-s2h*(1+zk))-v*zh)+zt)-v*zt)
 */

/* INDENT OFF */
/*
 * long double __k_clog_rl(long double x, long double y, long double *e);
 *
 * Compute real part of complex natural logarithm of x+iy in extra precision
 *
 * __k_clog_rl returns log(hypot(x, y)) with a correction term e.
 *
 * Accuracy: quad 140 bits, intel extended 91 bits.
 *
 * Method.
 * Assume X > Y >= 0 . Let X = 2**nx * x, Y = 2**nx * y, where 1 <= x < 2.
 * Let Z = X*X + Y*Y.  Then Z = 2**(nx+nx) * z, where z = x*x + y*y.
 * Note that z < 8.
 * Let Z = x*x + y*y.  Z can be normalized as Z = 2**N * z,  1 <= z < 2.
 * We further break down z into 1 + zk + zh + zt, where
 *      zk = K*(2**-7) matches z to 7.5 significant bits, 0 <= K <= 2**(-7)-1
 *      zh = (z-zk) rounded to half of the current significant bits
 *      zt = (z-zk-zh) rounded.
 *
 *         z - (1+zk)           (zh+zt)
 * Let s = ------------ = ---------------, then
 *         z + (1+zk)     2(1+zk)+zh+zt
 *                                                    z
 * log(Z) = N*log2 + log(z) = N*log2 + log(1+zk) + log(------)
 *                                                   1+zk
 *                                      1+s
```

```
 *        = N * log2 + log(1 +zk) + log(---)
 *                                      1-s
 *
 *                                           3             5
 *        = N*log2 + log(1+zk) +  2s +  1/12(2s)    +   1/80(2s)  + ...
 *
 *
 * Note 1. For IEEE double precision,  a fifteen degree odd polynomial
 *              2s + P1*(2s)^3 + P2*(2s)^5 + P3*(2s)^7 + ... + P7*(2s)^15
 *        is generated by a special remez algorithm to
 *        approx log((1+s)/(1-s)) accurte to 145 bits.
 * Note 2. 2s can be computed accurately as s2h+s2t by
 *        r = 2/((zh+zt)+2(1+zk))
 *        s2 = r*(zh+zt)
 *        s2h = s2 rounded to double;  v = 0.5*s2h;

171 /*
172 * Warning: cleverness ahead
173 *
174 * In the following code, the use of sprintf+write rather than fprintf
175 * to send output to the log file is intentional.  The reason is that
176 * fprintf is not async-signal-safe.  "But," you protest, "SIGFPE is
177 * not an asynchronous signal!  It's always handled by the same thread
178 * that executed the fpop that provoked it."  That's true, but a prob-
179 * lem arises because (i) base conversion in fprintf can cause a fp
180 * exception and (ii) my signal handler acquires a mutex lock before
181 * sending output to the log file (so that outputs for entries from
182 * different threads aren't interspersed).  Therefore, if the code
183 * were to use fprintf, a deadlock could occur as follows:
184 *
185 *       Thread A                        Thread B
186 *
187 *       Incurs a fp exception,          Calls fprintf,
188 *       acquires log_lock               acquires file rmutex lock
189 *
190 *       Calls fprintf,                  Incurs a fp exception,
191 *       waits for file rmutex lock      waits for log_lock
192 *
```

```
193 * (I could just verify that fprintf doesn't hold the rmutex lock while
194 * it's doing the base conversion, but since efficiency is of little
195 * concern here, I opted for the safe and dumb route.)

#if defined(ELFOBJ)
#pragma weak fmaxf = __fmaxf
#endif

/*
 * fmax(x,y) returns the larger of x and y.  If just one of the
 * arguments is NaN, fmax returns the other argument.  If both
 * arguments are NaN, fmax returns NaN (ideally, one of the
 * argument NaNs).
 *
 * C99 does not require that fmax(-0,+0) = fmax(+0,-0) = +0, but
 * ideally fmax should satisfy this.
 *
 * C99 makes no mention of exceptions for fmax.  I suppose ideally
 * either fmax never raises any exceptions or else it raises the
 * invalid operation exception if and only if some argument is a
 * signaling NaN.  In the former case, fmax should always return
 * one of its arguments.  In the latter, fmax shouldn't return a
 * signaling NaN, although when both arguments are signaling NaNs,
 * this ideal is at odds with the stipulation that fmax should
 * always return one of its arguments.
 *
 * Commutativity of fmax follows from the properties listed above
 * except when both arguments are NaN.  In that case, fmax may be
 * declared commutative by fiat because there is no portable way
 * to tell different NaNs apart.  Ideally fmax would be truly com-
 * mutative for all arguments.
 *
 * On SPARC V8, fmax must involve tests and branches.  Ideally,
 * an implementation on SPARC V9 should avoid branching, using
 * conditional moves instead where necessary, and be as efficient
```

```
 * as possible in its use of other resources.
 *
 * It appears to be impossible to attain all of the aforementioned
 * ideals simultaneously.  The implementation below satisfies the
 * following (on SPARC):
 *
 * 1. fmax(x,y) returns the larger of x and y if neither x nor y
 *    is NaN and the non-NaN argument if just one of x or y is NaN.
 *    If both x and y are NaN, fmax(x,y) returns x unchanged.
 * 2. fmax(-0,+0) = fmax(+0,-0) = +0.
 * 3. If either argument is a signaling NaN, fmax raises the invalid
 *    operation exception.  Otherwise, it raises no exceptions.
 */

/* INDENT OFF */
/*
 * True gamma function
 * double tgamma(double x)
 *
 * Error:
 * ------
 *      Less that one ulp for both positive and negative arguments.
 *
 * Algorithm:
 * ---------
 *      A: For negative argument
 *              (1) gamma(-n or -inf) is NaN
 *              (2) Underflow Threshold
 *              (3) Reduction to gamma(1+x)
 *      B: For x between 1 and 2
 *      C: For x between 0 and 1
 *      D: For x between 2 and 8
 *      E: Overflow thresold {see over.c}
 *      F: For overflow_threshold >= x >= 8
 *
 * Implementation details
 * ----------------------
 *                                                          -pi
 * (A) For negative argument, use gamma(-x) = ------------------------.
```

```
 *                                          (sin(pi*x)*gamma(1+x))
 *
 *   (1) gamma(-n or -inf) is NaN with invalid signal by SUSv3 spec.
 *       (Ideally, gamma(-n) = 1/sinpi(n) = (-1)**(n+1) * inf.)
 *
 *   (2) Underflow Threshold. For each precision, there is a value T
 *       such that when x>T and when x is not an integer, gamma(-x) will
 *        always underflow. A table of the underflow threshold value is given
 *       below. For proof, see file "under.c".
 *
 *       Precision       underflow threshold T =
 *       ------------------------------------------------------------------------
 *       single  41.000041962                                    = 41  + 11 ULP
 *               (machine format) 4224000B
 *       double  183.00000000000312639                           = 183 + 11 ULP
 *               (machine format) 4066E000 0000000B
 *       quad    1774.00000000000000000000000000017749370      = 1774 + 9 ULP
 *               (machine format) 4009BB8000000000000000000000009
 *       ------------------------------------------------------------------------
 *
 *   (3) Reduction to gamma(1+x).
 *       Because of (1) and (2), we need only consider non-integral x
 *       such that 0<x<T. Let k = [x] and z = x-[x]. Define
 *                    sin(x*pi)                  cos(x*pi)
 *       kpsin(x) = --------- and kpcos(x) = --------- . Then
 *                      pi                         pi
 *                                  1
 *              gamma(-x) = --------------------.
 *                          -kpsin(x)*gamma(1+x)
 *       Since x = k+z,
 *                                                  k+1
 *              -sin(x*pi) = -sin(k*pi+z*pi) = (-1)   *sin(z*pi),
 *                                 k+1
 *       we have -kpsin(x) = (-1)   * kpsin(z).  We can further
 *       reduce z to t by
 *          (I)   t = z       when 0.00000     <= z < 0.31830...
 *          (II)  t = 0.5-z   when 0.31830...  <= z < 0.681690...
 *          (III) t = 1-z     when 0.681690... <= z < 1.00000
 *       and correspondingly
 *          (I)   kpsin(z) = kpsin(t)    ... 0<= z < 0.3184
 *          (II)  kpsin(z) = kpcos(t)    ... |t|   < 0.182

187  *      Computation note: in simulating higher precision arithmetic, kcpcos
188  *      return head = 1/pi chopped, and tail = pi/2 *t^2 + (tail part of 1/pi
189  *      + ...) to maintain extra bits precision. In particular, pi/2 * t^2
190  *      is calculated with great care.
```

```
191  *
192  *      Thus, the computation of gamma(-x), x>0, is:
193  *      Let k = int(x), z = x-k.
194  *      For z in (I)
195  *                                      k+1
196  *                                  (-1)
197  *              gamma(-x) = ------------------- ;
198  *                          kpsin(z)*gamma(1+x)
199  *
200  *      otherwise, for z in (II),
201  *                                      k+1
202  *                                  (-1)
203  *              gamma(-x) = ---------------------- ;
204  *                          kpcos(0.5-z)*gamma(1+x)
205  *
206  *      otherwise, for z in (III),
207  *                                      k+1
208  *                                  (-1)
209  *              gamma(-x) = -------------------- .
210  *                          kpsin(1-z)*gamma(1+x)
211  *
212  *      Thus, the computation of gamma(-x) reduced to the computation of
213  *      gamma(1+x) and kpsin(), kpcos().
214  *
215  * (B) For x between 1 and 2.  We break [1,2] into three parts:

 430  *
 431  * (C) For x between 0 and 1.
 432  *     Let P stand for the number of significant bits in the working precision.
 433  *                                -P                                  1
 434  *    (1)For 0 <= x <= 2   , gamma(x) is computed by --- rounded to nearest.
 435  *                                                    x
 436  *       The error is bound by 0.739 ulp(gamma(x)) in IEEE double precision.
 437  *      Proof.
 438  *                 1                          2
 439  *      Since  --------  ~  x + 0.577...*x  - ...,  we have, for small x,
 440  *             gamma(x)
 441  *           1                    1
 442  *      ----------- < gamma(x) < --- and
 443  *      x(1+0.578x)               x
 444  *             1                  1          1
 445  *        0 <  --- - gamma(x) <= ---  -  ----------- < 0.578
 446  *             x                  x      x(1+0.578x)
 447  *                                  1       1                          -P
 448  *      The error is thus bounded by --- ulp(---) + 0.578. Since x <= 2   ,
 449  *                                  2       x
 450  *       1      P       1           P                                     1
 451  *      --- >= 2 , ulp(---) >= ulp(2  ) >= 2. Thus 0.578=0.289*2<=0.289ulp(-)
 452  *       x             x                                                 x
 453  *       Thus
 454  *                              1                                     1
```

```
 455  *                | gamma(x) - [---] rounded | <= (0.5+0.289)*ulp(---).
 456  *                                  x                                 x
 457  *                             -P                                    1
 458  *      Note that for x<= 2  , it is easy to see that ulp(---)=ulp(gamma(x))
 459  *                                                                    x
 460  *                               n                                   1
 461  *      except only when x = 2 , (n<= -53). In such cases, --- is exact
 462  *                                                                    x
 463  *      and therefore the error is bounded by
 464  *                                1
 465  *              0.298*ulp(---) = 0.298*2*ulp(gamma(x)) = 0.578ulp(gamma(x)).
 466  *                               x
 467  *      Thus we conclude that the error in gamma is less than 0.739 ulp.
 468  *
 469  *    (2)Otherwise, for x in GTi-1 (see B), let y = x-(zi-1). From (B) we obtain
 470  *                                                                  gamma(1+x)
 471  *      gamma(1+x) = gy.h + gy.l,  then compute gamma(x) by -----------.
 472  *                                                                    x
 473  *                                                                  gy.h
 474  *      Implementaion note. Write x = x.h+x.l, and Let th = ----- chopped to
 475  *                                                                   x
 476  *      20 bits, then
 477  *                                  gy.h+gy.l
 478  *              gamma(x) = th + (----------  - th )
 479  *                                     x
 480  *                                   1
 481  *                        = th + ---*(gy.h-th*x.h+gy.l-th*x.l)
 482  *                                   x
 483  *
 484  * (D) For x between 2 and 8. Let n = 1+x chopped to an integer. Then
 485  *
 486  *                gamma(x)=(x-1)*(x-2)*...*(x-n)*gamma(x-n)
 487  *
 488  *     Since x-n is between 1 and 2, we can apply (B) to compute gamma(x).
 489  *
 490  *     Implementation detail. The computation of (x-1)(x-2)...(x-n) in simulated
 491  *     higher precision arithmetic can be somewhat optimized.  For example, in
 492  *     computing (x-1)*(x-2)*(x-3)*(x-4), if we compute (x-1)*(x-4) = z.h+z.l,
 493  *     then (x-2)(x-3) = z.h+2+z.l readily. In below, we list the expression
 494  *     of the formula to compute gamma(x).
 495  *
 496  *     Assume x-n is in GTi (i=1,2, or 3, see B for detail). Let y = x - n - zi.
 497  *     By (B) we have gamma(x-n) = gy.h+gy.l. If x = x.h+x.l, then we have
 498  *      n=1 (x in [2,3]):
 499  *       gamma(x) = (x-1)*gamma(x-1) = (x-1)*(gy.h+gy.l)
 500  *                = [(x.h-1)+x.l]*(gy.h+gy.l)
 501  *      n=2 (x in [3,4]):
 502  *        gamma(x) = (x-1)(x-2)*gamma(x-2) = (x-1)*(x-2)*(gy.h+gy.l)
 503  *                 = ((x.h-2)+x.l)*((x.h-1)+x.l)*(gy.h+gy.l)
 504  *                 = [x.h*(x.h-3)+2+x.l*(x+(x.h-3))]*(gy.h+gy.l)
 505  *      n=3 (x in [4,5])
 506  *       gamma(x) = (x-1)(x-2)(x-3)*(gy.h+gy.l)
 507  *                = (x.h*(x.h-3)+2+x.l*(x+(x.h-3)))*[((x.h-3)+x.l)(gy.h+gy.l)]
 508  *      n=4 (x in [5,6])
 509  *       gamma(x) = [(x-1)(x-4)]*[(x-2)(x-3)]*(gy.h+gy.l)
 510  *                = [(x.h*(x.h-5)+4+x.l(x+(x.h-5)))]*[(x-2)*(x-3)]*(gy.h+gy.l)
 511  *                = (y.h+y.l)*(y.h+1+y.l)*(gy.h+gy.l)
 512  *      n=5 (x in [6,7])
 513  *       gamma(x) = [(x-1)(x-4)]*[(x-2)(x-3)]*[(x-5)*(gy.h+gy.l)]
 514  *      n=6 (x in [7,8])
 515  *       gamma(x) = [(x-1)(x-6)]*[(x-2)(x-5)]*[(x-3)(x-4)]*(gy.h+gy.l)]
 516  *                = [(y.h+y.l)(y.h+4+y.l)][(y.h+6+y.l)(gy.h+gy.l)]
 517  *
 518  * (E)Overflow Thresold. For x > Overflow thresold of gamma,
 519  *    return huge*huge (overflow).
 520  *
```

```
 *    By checking whether lgamma(x) >= 2**{128,1024,16384}, one can
 *    determine the overflow threshold for x in single, double, and
 *    quad precision. See over.c for details.
 *
 *    The overflow threshold of gamma(x) are
 *
 *    single: x = 3.5040096283e+01
 *              = 0x420C290F (IEEE single)
 *    double: x = 1.71624376956302711505e+02
 *              = 0x406573FAE561F647 (IEEE double)
 *    quad:   x = 1.75554834290446291700388921607020320341 77e+03
 *              = 0x4009B6E3180CD66A5C4206F128BA77F4  (quad)
 *
 * (F)For overflow_threshold >= x >= 8, we use asymptotic approximation.
 *    (1) Stirling's formula
 *
 *      log(G(x)) ~= (x-.5)*(log(x)-1) + .5(log(2*pi)-1) + (1/x)*P(1/(x*x))
 *                 = L1 + L2 + L3,
 *    where
 *              L1(x) = (x-.5)*(log(x)-1),
 *              L2    = .5(log(2pi)-1) = 0.41893853....,
 *              L3(x) = (1/x)P(1/(x*x)),
 *
 *    The range of L1,L2, and L3 are as follows:
 *
 *      ------------------------------------------------------------------
 *      Range(L1) =  (single) [8.09..,88.30..]   =[2** 3.01..,2**  6.46..]
 *                   (double) [8.09..,709.3..]   =[2** 3.01..,2**  9.47..]
 *                   (quad)   [8.09..,11356.10..]=[2** 3.01..,2** 13.47..]
 *      Range(L2) = 0.41893853.....
 *      Range(L3) = [0.0104...., 0.00048....]    =[2**-6.58..,2**-11.02..]
 *      ------------------------------------------------------------------
 *
 *    Gamma(x) is then computed by exp(L1+L2+L3).
 *
 *    (2) Error analysis of (F):
 *    --------------------------
 *    The error in Gamma(x) depends on the error inherited in the computation
 *    of L= L1+L2+L3. Let L' be the computed value of L. The absolute error
 *    in L' is t = L-L'. Since exp(L') = exp(L-t) = exp(L)*exp(t) ~
 *    (1+t)*exp(L), the relative error in exp(L') is approximately t.
 *
 *    To guarantee the relatively accuracy in exp(L'), we would like
 *    |t| < 2**(-P-5) where P denotes for the number of significant bits
 *    of the working precision. Consequently, each of the L1,L2, and L3
 *    must be computed with absolute error bounded by 2**(-P-5) in absolute
 *    value.
 *
 *    Since L2 is a constant, it can be pre-computed to the desired accuracy.
 *    Also |L3| < 2**-6; therefore, it suffices to compute L3 with the
 *    working precision.  That is,
 *      L3(x) approxmiate log(G(x))-(x-.5)(log(x)-1)-.5(log(2pi)-1)
 *    to a precision bounded by 2**(-P-5).
 *
 *                                  2**(-6)
 *                              _____V_____________________
 *              L1(x):     |_____|_____|_____|
 *                                 __ _____________________
 *              L2:              |__|_____|_____|
 *                                  _____________________
 *         +    L3(x):              |_____|_____|
 *                        ----------------------------------------
 *                          [leading] + [Trailing]
 *
 *    For L1(x)=(x-0.5)*(log(x)-1), we need ilogb(L1(x))+5 extra bits for
 *    both multiplicants to guarantee L1(x)'s absolute error is bounded by
```

```
 *    2**(-P-5) in absolute value. Here ilogb(y) is defined to be the unbias
 *    binary exponent of y in IEEE format.  We can get x-0.5 to the desire
 *    accuracy easily. It remains to compute log(x)-1 with ilogb(L1(x))+5
 *    extra bits accracy. Note that the range of L1 is 88.30.., 709.3.., and
 *    11356.10... for single, double, and quadruple precision, we have
 *
 *                             single     double      quadruple
 *                           ------------------------------------
 *      ilogb(L1(x))+5 <=      11          14           18
 *                           ------------------------------------
 *
 *    (3) Table Driven Method for log(x)-1:
 *    -------------------------------------
 *    Let x = 2**n * y, where 1 <= y < 2. Let Z={z(i),i=1,...,m}
 *    be a set of predetermined evenly distributed floating point numbers
 *    in [1, 2]. Let z(j) be the closest one to y, then
 *      log(x)-1 = n*log(2)-1  +  log(y)
 *               = n*log(2)-1  +  log(z(j)*y/z(j))
 *               = n*log(2)-1  +  log(z(j))  +  log(y/z(j))
 *               = T1(n)       +  T2(j)      +  T3,
 *
 *    where T1(n) = n*log(2)-1 and T2(j) = log(z(j)). Both T1 and T2 can be
 *    pre-calculated and be looked-up in a table. Note that 8 <= x < 1756
 *    implies 3<=n<=10 implies 1.079.. < T1(n) < 6.931.
 *
 *
 *                      y-z(i)           y       1+s
 *    For T3, let s = --------; then ----- =  ----- and
 *                      y+z(i)         z(i)      1-s
 *                 1+s              2   3     2   5
 *        T3 = log(-----) = 2s + --- s  + --- s  + ....
 *                 1-s              3       5
 *
 *    Suppose the first term 2s is compute in extra precision. The
 *    dominating error in T3 would then be the rounding error of the
 *    second term 2/3*s**3. To force the rounding bounded by
 *    the required accuracy, we have
 *        single:  |2/3*s**3| < 2**-11  ==> |s|<0.09014...
 *        double:  |2/3*s**3| < 2**-14  ==> |s|<0.04507...
 *        quad  :  |2/3*s**3| < 2**-18  ==> |s|<0.01788... = 2**(-5.80..)
 *
 *    Base on this analysis, we choose Z = {z(i)|z(i)=1+i/64+1/128, 0<=i<=63}.
 *    For any y in [1,2), let j = [64*y] chopped to integer, then z(j) is
 *    the closest to y, and it is not difficult to see that |s| < 2**(-8).
 *    Please note that the polynomial approximation of T3 must be accurate
 *        -24-11   -35    -53-14    -67         -113-18   -131
 *    to 2       =2    ,  2       = 2    ,  and  2        =2
 *    for single, double, and quadruple precision respectively.
 *
 *    Inplementation notes.
 *    (1) Table look-up entries for T1(n) and T2(j), as well as the calculation
 *        of the leading term 2s in T3,  are broken up into leading and trailing
 *        part such that (leading part)* 2**24 will always be an integer. That
 *        will guarantee the addition of the leading parts will be exact.
 *
 *                                     2**(-24)
 *                                 _____V_____________________
 *              T1(n):     |_____|_____|_____|
 *                                  _____ _____________________
 *              T2(j):       |_____|_____|_____|
 *                                   ____ _____________________
 *              2s:              |____|_____|_____|
 *                                  _____________________
 *         +    T3(s)-2s:           |_____|_____|
 *                          ----------------------------------------

```

```
653  *
654  *    (2) How to compute 2s accurately.
655  *        (A) Compute v = 2s to the working precision. If |v| < 2**(-18),
656  *            stop.
657  *        (B) chopped v to 2**(-24): v = ((int)(v*2**24))/2**24
658  *        (C) 2s = v + (2s - v), where
659  *                          1
660  *                2s - v = --- * (2(y-z) - v*(y+z) )
661  *                         y+z
662  *                           1
663  *                        = --- * ( [2(y-z) - v*(y+z)_h ]  - v*(y+z)_l  )
664  *                         y+z
665  *             where (y+z)_h = (y+z) rounded to 24 bits by (double)(float),
666  *           and (y+z)_l = ((z+z)-(y+z)_h)+(y-z).  Note the the quantity
667  *           in [] is exact.
668  *                                                          2        4
669  *    (3) Remez approximation for (T3(s)-2s)/s = T3[0]*s + T3[1]*s + ...:
670  *       Single precision: 1 term (compute in double precision arithmetic)
671  *          T3(s) = 2s + S1*s^3, S1 = 0.66667172318485180546936236975392 30
672  *          Remez error: |T3(s)/s - (2s+S1*s^3)| < 2**(-35.87)
673  *       Double precision: 3 terms, Remez error is bounded by 2**(-72.40),
674  *          see "tgamma_log"
675  *       Quad precision: 7 terms, Remez error is bounded by 2**(-136.54),
676  *          see "tgammal_log"
677  *
678  *    The computation of 0.5*(ln(2pi)-1):
679  *       0.5*(ln(2pi)-1) =  0.41893853320467274178032973640561763986 14...
680  *       split 0.5*(ln(2pi)-1) to hln2pi_h + hln2pi_l, where hln2pi_h is the
681  *       leading 21 bits of the constant.
682  *          hln2pi_h= 0.418938398361206054687 5

/ Note: 0^NaN should not signal "invalid" but this implementation
/ does because y is placed on the NPX stack.

/ Special cases:
/
/ x ** 0 is 1                           _SVID_libm_err if x is 0 or NaN
/ 1 ** y is 1                           (C99)
/ x ** NaN is NaN
/ NaN ** y (except 0) is NaN
/ x ** 1 is x
/ +-(|x| > 1) **  +inf is +inf
/ +-(|x| > 1) **  -inf is +0
/ +-(|x| < 1) **  +inf is +0
/ +-(|x| < 1) **  -inf is +inf
/ (-1) ** +-inf is +1                   (C99)
/ +0 ** +y (except 0, NaN)              is +0
/ -0 ** +y (except 0, NaN, odd int)     is +0
/ -0 ** +y (odd int)                    is -0
/ +-0 ** -y (except 0, NaN)             _SVID_libm_err
/ +inf ** +y (except 0, NaN)            is +inf
/ +inf ** -y (except 0, NaN)            is +0
/ -inf ** +-y (except 0, NaN)           is -0 ** -+y (NO z flag)
/ x ** -1 is 1/x
/ x ** 2 is x*x
/ -x ** y (an integer) is (-1)**(y) * (+x)**(y)
/ x ** y (x negative & y not integer)   _SVID_libm_err
/ if x and y are finite and x**y = 0    _SVID_libm_err (underflow)
/ if x and y are finite and x**y = inf  _SVID_libm_err (overflow)

/ Note: 0^SNaN should not signal "invalid" but this implementation
/ does because y is placed on the NPX stack.

/ Special cases:
/
/ x ** 0 is 1
/ 1 ** y is 1                           (C99)
/ x ** NaN is NaN
/ NaN ** y (except 0) is NaN
/ x ** 1 is x
/ +-(|x| > 1) **  +inf is +inf
/ +-(|x| > 1) **  -inf is +0
/ +-(|x| < 1) **  +inf is +0
/ +-(|x| < 1) **  -inf is +inf
/ (-1) ** +-inf is +1                   (C99)
/ +0 ** +y (except 0, NaN)              is +0
/ -0 ** +y (except 0, NaN, odd int)     is +0
/ +0 ** -y (except 0, NaN)              is +inf (z flag)
/ -0 ** -y (except 0, NaN, odd int)     is +inf (z flag)
/ -0 ** y (odd int)                     is - (+0 ** x)
/ +inf ** +y (except 0, NaN)            is +inf
/ +inf ** -y (except 0, NaN)            is +0
/ -inf ** +-y (except 0, NaN)           is -0 ** -+y (NO z flag)
/ x ** -1 is 1/x
/ x ** 2 is x*x
/ -x ** y (an integer) is (-1)**(y) * (+x)**(y)
/ x ** y (x negative & y not integer) is NaN (i flag)

/*
 * __vexp: double precision vector exp
 *
 * Algorithm:
 *
 * Write x = (k + j/256)ln2 + r, where k and j are integers, j >= 0,
 * and |r| <= ln2/512.  Then exp(x) = 2^k * 2^(j/256) * exp(r).
 * Compute exp(r) by a polynomial approximation exp(r) ~ 1 + p(r)
 * where p(r) := r*(1+r*(B1+r*(B2+r*B3))).  From a table, obtain
 * h and l such that h ~ 2^(j/256) to double precision and h+l
 * ~ 2^(j/256) to well more than double precision.  Then exp(x)
 * ~ 2^k * (h + (l + h * p(r))) to about double precision.  Note
 * that the multiplication by 2^k requires some finagling when
 * the result might be subnormal.
 *
 * Accuracy:
 *
 * For normal results, the largest error observed is less than
 * 0.6 ulps.  For subnormal results, the largest error observed
 * is 0.737 ulps.
 */

/* float expf(float x)
 *
 * Method :
 *      1. Special cases:
 *              for x > 88.722839355...(0x42B17218) => Inf + overflow;
 *              for x < -103.97207642..(0xc2CFF1B4) => 0 + underflow;
 *              for x = Inf                         => Inf;
 *              for x = -Inf                        => 0;
 *              for x = +-NaN                       => QNaN.
 *      2. Computes exponential from:
 *              exp(x) = 2**a  *  2**(k/256)  *  2**(y/256)
 *      Where:
 *              a    =    int  ( 256 * log2(e) * x ) >> 8;
 *              k    =    int  ( 256 * log2(e) * x ) & 0xFF;
 *              y    =    frac ( 256 * x * log2(e)).
 *      Note that:
 *              k = 0, 1, ..., 255;
 *              y = (-1, 1).
 *      Then:
 *              2**(k/256) is looked up in a table of 2**0, 2**1/256, ...
 *              2**(y/256) is computed using approximation:
 *                      2**(y/256) =  a0 + a1 * y + a2 * y**2
 *              Multiplication by 2**a is done by adding "a" to
 *              the biased exponent.
 * Accuracy:
 *      The maximum relative error for the approximating
```

```
 *      polynomial is 2**(-29.18).  All calculations are of
 *      double precision.
 *      Maximum error observed: less than 0.528 ulp for the whole
 *      float type range.
 *
 * NOTE: This implementation has been modified for SPARC to deliver
 * zero instead of a subnormal result whenever the argument is less
 * than log(2^-126).  Therefore the worst case relative error is 1.
 */

/*
 * __vlog: double precision vector log
 *
 * Algorithm:
 *
 * Write x = 2^n z where 1 - 2^-10 <= z < 2 - 2^-9.  Let m = z
 * rounded to nine significant bits, so m = 1 + 2^-8 k, where
 * 0 <= k <= 255.  Let d = z - m.  Then
 *
 * log(x) = n log(2) + log(m) + log(1+(d/m))
 *
 * Let ln2hi = log(2) rounded to a multiple of 2^-42 and ln2lo
 * ~ log(2) - ln2hi.  From a table, obtain mh and ml such that
 * mh = log(m) rounded to a multiple of 2^-42 and ml ~ log(m) -
 * mh.  From the same table, obtain rh and rl such that rh = 1/m
 * rounded to a multiple of 2^-10 and rl ~ 1/m - rh.  For |y| <=
 * 2^-9, approximate log(1+y) by a polynomial y+p(y) where p(y)
 * := y*y*(-1/2+y*(P3+y*(P4+y*(P5+y*P6)))).  Now letting s =
 * d*rh + d*rl in double precision, we can compute the sum above
 * accurately as
 *
 * (n*ln2hi + mh) + (d*rh + (d*rl + (n*ln2lo + ml) + p(s)))
 *
 * When x is subnormal, we first scale it to the normal range,
 * adjusting n accordingly.
 *
 * Accuracy:
 *
 * The largest error observed is less than 0.8 ulps.

/* float logf(float x)
 *
 * Method :
 *      1. Special cases:
 *              for x is negative, -Inf => QNaN + invalid;
 *              for x = 0               => -Inf + divide-by-zero;
 *              for x = +Inf            => Inf;
 *              for x = NaN             => QNaN.
 *      2. Computes logarithm from:
 *              x = m * 2**n => log(x) = n * log(2) + log(m),
 *              m = [1, 2).
 *      Let m = m0 + dm, where m0 = 1 + k / 32,
 *              k = [0, 32],
 *              dm = [-1/64, 1/64].
 *      Then log(m) = log(m0 + dm) = log(m0) + log(1+y),
 *              where y = dm*(1/m0), y = [-1/66, 1/64].
 *      Then
 *              1/m0 is looked up in a table of 1, 1/(1+1/32), ..., 1/(1+32/32);
 *              log(m0) is looked up in a table of log(1), log(1+1/32),
 *              ..., log(1+32/32).
 *              log(1+y) is computed using approximation:
 *              log(1+y) = ((a3*y + a2)*y + a1)*y*y + y.
 * Accuracy:
 *      The maximum relative error for the approximating
 *      polynomial is 2**(-28.41).  All calculations are of
 *      double precision.
```

```
 *      Maximum error observed: less than 0.545 ulp for the
 *      whole float type range.

 *              for +Inf ** (negative)                          => +0
 *              for +Inf ** (positive)                          => +Inf
 *              for -Inf ** (negative except odd integer)       => +0
```

```
 *              for -Inf ** (negative odd integer)              => -0
 *              for -Inf ** (positive except odd integer)       => +Inf
 *              for -Inf ** (positive odd integer)              => -Inf
 *              for (negative) ** (non-integer)                 => QNaN + invali
 *              for +0 ** (negative)                            => +Inf + overfl
 *              for +0 ** (positive)                            => +0
 *              for -0 ** (negative except odd integer)         => +Inf + overfl
 *              for -0 ** (negative odd integer)                => -Inf + overfl
 *              for -0 ** (positive except odd integer)         => +0
 *              for -0 ** (positive odd integer)                => -0
 *      2. Computes x**y from:
 *              x**y = 2**(y*log2(x)) = 2**(w/256), where w = 256*log2(|x|)*y.
 *      3. Computes w = 256*log2(|x|)*y from
 *              |x| = m * 2**n => log2(|x|) = n + log2(m).
 *      Let m = m0 + dm, where m0 = 1 + k / 256,
 *              k = [0, 255],
 *              dm = [-1/512, 1/512].
 *      Then 256*log2(m) = 256*log2(m0 + dm) = 256*log2(m0) + 256*log2((1+z)/(1-
 *              where z = (m-m0)/(m+m0), z = [-1/1025, 1/1025].
 *      Then
 *              256*log2(m0) is looked up in a table of 256*log2(1), 256*log2(1+
 *                      ..., 256*log2(1+128/128).
 *              256*log2((1+z)/(1-z)) is computed using
 *                      approximation: 256*log2((1+z)/(1-z)) = a0 * z + a1 * z**
 *      Perform w = 256*log2(|x|)*y = w1 + w2 by simulating muti-precision arith
 *      3. For w >= 262144
 *              then for (negative) ** (odd integer)    => -Inf + overflow
 *              else                                    => +Inf + overflow
 *      For w <= -275200
 *              then for (negative) ** (odd integer)    => -0 + underflow
 *              else                                    => +0 + underflow
 *      4. Computes 2 ** (w/256) from:
 *              2 ** (w/256) = 2**a  *  2**(k/256)  *  2**(r/256)
 *      Where:
 *              a    =    int  ( w ) >> 8;
 *              k    =    int  ( w ) & 0xFF;
 *              r    =    frac ( w ).
 *      Note that:
 *              k = 0, 1, ..., 255;
 *              r = (-1, 1).
 *      Then:
 *              2**(k/256) is looked up in a table of 2**0, 2**1/256, ...
 *              2**(r/256) is computed using approximation:
 *                      2**(r/256) =  ((((b5 * r + b4) * r + b3) * r + b2) * r +
 *              Multiplication by 2**a is done by adding "a" to
 *              the biased exponent.
 *      Perform 2 ** (w/256) by simulating muti-precision arithmetic.
 *      5. For (negative) ** (odd integer)              => -(2**(w/256))
 *      otherwise                                       =>   2**(w/256)
 *
 * Accuracy:
 *      Max. relative aproximation error < 2**(-67.94) for 256*log2((1+z)/(1-z))
 *      Max. relative aproximation error < 2**(-63.15) for 2**(r/256).
 *      Maximum error observed: less than 0.761 ulp after 1.300.000.000
 *      results.
