  32 #       Note that libcurses installs commands along with its library.
  33 #       This is a minor bug which probably should be fixed.
  34 #       Note also that a few extra libraries are kept in cmd source.
  35 #
  36 # Certain libraries are linked with, hence depend on, other libraries.
  37 #
  38 # Although we have historically used .WAIT to express dependencies, it
  39 # reduces the amount of parallelism and thus lengthens the time it
  40 # takes to build the libraries.  Thus, we now require that any new
  41 # libraries explicitly call out their dependencies.  Eventually, all
  42 # the library dependencies will be called out explicitly.  See
  43 # "Library interdependencies" near the end of this file.
  44 #
  45 # Aside from explicit dependencies (and legacy .WAITs), all libraries
  46 # are built in parallel.
  47 #
  48 .PARALLEL:

530 .KEEP_STATE:

532 #
533 # For the all and install targets, we clearly must respect library
534 # dependencies so that the libraries link correctly.  However, for
535 # the remaining targets (check, clean, clobber, install_h, lint, _dc
536 # and _msg), libraries do not have any dependencies on one another
537 # and thus respecting dependencies just slows down the build.
538 # As such, for these rules, we use pattern replacement to explicitly
539 # avoid triggering the dependency information.  Note that for clean,
540 # clobber and lint, we must use $(NOWAIT_SUBDIRS) rather than
541 # $(SUBDIRS), to prevent '.WAIT' from expanding to '.WAIT-nodepend'.
542 #

#
# We want to build hardware specific versions of the longest_match()
# function into our shared library that has been hand optimised to use
# some machine architecture specific instructions. Currently, we are doing
# it for the T4 architecture, but later other architectures may be added.
# This is done by taking advantage of the Solaris 11 linker-editor
# "Symbol Capabilities" feature.  Refer to the section "Creating a Family
# of Symbol Capabilities Functions", under "Identifying Capability
# Requirements" in the "Linker and Libraries Guide"
# (http://docs.oracle.com/cd/E19963-01/html/819-0690/chapter2-13.html#giskh).

1002 Integrate zlib
**********************************************************
```

```
   1                Creation of the zlib source for illumos

   4 This source was derived from the Oracle userland version of zlib.
   5 Their userland distribution is documented at:

   7     https://java.net/projects/solaris-userland

   9 Use this command to obtain it:

  11     $ hg clone https://hg.java.net/hg/solaris-userland~gate userland-gate

  13 It includes adaptations for all opensource software that's included
  14 with Oracle Solaris, along with download procedures and build
  15 procedures.  It will download and build zlib-1.2.8.tar.gz in the
  16 components/zlib directory.

  18 Begin by building the userland version of zlib.  I had to modify some
  19 of the userland files to accomodate the older versions of python,
  20 perl, and ld on illumos distributions.  The different location of the
  21 compilers also had to be accomodated.  For the userland build on
  22 SPARC, I also had to omit Oracle's T4 capability enhancements because
  23 they used compiler options that were not available on illumos
  24 distributions, specifically these:

  26     -xarch=sparc4 -xtarget=T4 -xchip=T4

  28 Once the userland build is complete, record the compiler options so
  29 they can be transferred to the illumos build.

  31 The location for illumos is usr/src/lib/zlib .  Makefiles follow the
  32 model described in usr/src/lib/README.Makefiles .  At the top level of
  33 the new subdirectory, both Makefile and Makefile.com are required.  In
  34 the ISA-dependant locations (amd64 i386 sparc sparcv9), only Makefile
  35 is required.  All of the zlib source goes in the 'common' directory.

  37 Most of the files from the zlib userland directory are copied to the
  38 new location.  'capabilities' is copied, but used only for reference.
  39 'llib-lz' becomes a symlink target.  'Makefile' is renamed and used
  40 only for reference.  'mapfile' is also a symlink target.  'patches' is
  41 copied, but 'parfait.patch' is moved to the new 'unused-patches'
  42 directory.  'zlib-1.2.8' is moved to 'common'.  This source has already
  43 been patched by the userland build.  'zlib.3.sunman' is
  44 used only for reference.  'zlib.license' becomes a symlink target.
  45 'zlib.p5m', the manifest, is renamed and used for reference.

  47 The 'build' directory and the file 'zlib-1.2.8.tar.gz' are not used
  48 and don't need to be copied.  None of the Oracle or zlib Makefiles
  49 are used, except for reference.  The following files, symlinks, or
  50 directories are newly created in the new illumos location:

  52     unused-patches THIRDPARTYLICENSE THIRDPARTYLICENSE.descrip
  53     amd64 common i386 sparc sparcv9
  54     common/llib-lz common/mapfile-vers

  56 The new Makefiles list all the object files, suppress the header
  57 check, add the necessary compile options, and create usr symlinks in
  58 the prototype area.

  60 The zlib man pages are installed by an addition to the Makefile in
```

```
  61 usr/src/man/man3 .  Rather than copy the man page source to this
  62 location, a symlink pointing to common/zlib.3 is created here.

  64 A new manifest, library-zlib.mf, is created in usr/src/pkg/manifests
  65 to build the IPS package from files in the prototype area.
```

```
   1 !
   2 ! This file was generated by a compiler that is currently not part of the CBE
   3 ! (as the CBE compiler does not generate code for the T4 architecture), and
   4 ! then it was modified by hand to remove some unnecessary instructions that
   5 ! the compiler generated and the main loop's branches was rearranged for
   6 ! fewer taken branches on the most frequent code path. These modifications
   7 ! were made in 7 steps. In each step, a few lines were removed from and added
   8 ! to the compiler generated code to produce an equivalent binary. The lines
   9 ! that were removed in step <i> are marked by "!<i>" at the beginning of the
  10 ! line, the lines added in this step are marked by the same added at the end of
  11 ! the line. In other words, let C_i mean the code, after step <i> (C_0 is
  12 ! the original, compiler generated code, C_7 is the code in this file)
  13 ! To reproduce C_i (0 <= i < 7) first take C_<i+1>, remove the lines that
  14 ! end in !<i+1>, and then remove the !<i+1> string from the beginning of those
  15 ! lines that start with it. Comparing C_i and C_<i+1> is a simple task, as
  16 ! only a few lines have changed.
  17 !  If a compiler (e.g. the Oracle Studio 12.3) becomes part of the CBE and
  18 ! it will be able to generate as efficient code as in this file the
  19 ! longest_match.o file can simply be comp[iled from longest_match.c .

5470 libz should be part of illumos
1002 Integrate zlib
**********************************************************
```

```
  2                 ChangeLog file for zlib

  4 Changes in 1.2.8 (28 Apr 2013)
  5 - Update contrib/minizip/iowin32.c for Windows RT [Vollant]
  6 - Do not force Z_CONST for C++
  7 - Clean up contrib/vstudio [Ro´§]
  8 - Correct spelling error in zlib.h
  9 - Fix mixed line endings in contrib/vstudio

 11 Changes in 1.2.7.3 (13 Apr 2013)
 12 - Fix version numbers and DLL names in contrib/vstudio/*/zlib.rc

 14 Changes in 1.2.7.2 (13 Apr 2013)
 15 - Change check for a four-byte type back to hexadecimal
 16 - Fix typo in win32/Makefile.msc
 17 - Add casts in gzwrite.c for pointer differences

 19 Changes in 1.2.7.1 (24 Mar 2013)
 20 - Replace use of unsafe string functions with snprintf if available
 21 - Avoid including stddef.h on Windows for Z_SOLO compile [Niessink]
 22 - Fix gzgetc undefine when Z_PREFIX set [Turk]
 23 - Eliminate use of mktemp in Makefile (not always available)
 24 - Fix bug in 'F' mode for gzopen()
 25 - Add inflateGetDictionary() function
 26 - Correct comment in deflate.h
 27 - Use _snprintf for snprintf in Microsoft C
 28 - On Darwin, only use /usr/bin/libtool if libtool is not Apple
 29 - Delete "--version" file if created by "ar --version" [Richard G.]
 30 - Fix configure check for veracity of compiler error return codes
 31 - Fix CMake compilation of static lib for MSVC2010 x64
 32 - Remove unused variable in infback9.c
 33 - Fix argument checks in gzlog_compress() and gzlog_write()
 34 - Clean up the usage of z_const and respect const usage within zlib
 35 - Clean up examples/gzlog.[ch] comparisons of different types
 36 - Avoid shift equal to bits in type (caused endless loop)
 37 - Fix unintialized value bug in gzputc() introduced by const patches
 38 - Fix memory allocation error in examples/zran.c [Nor]
 39 - Fix bug where gzopen(), gzclose() would write an empty file
 40 - Fix bug in gzclose() when gzwrite() runs out of memory
 41 - Check for input buffer malloc failure in examples/gzappend.c
 42 - Add note to contrib/blast to use binary mode in stdio
 43 - Fix comparisons of differently signed integers in contrib/blast
 44 - Check for invalid code length codes in contrib/puff
 45 - Fix serious but very rare decompression bug in inftrees.c
 46 - Update inflateBack() comments, since inflate() can be faster
 47 - Use underscored I/O function names for WINAPI_FAMILY
 48 - Add _tr_flush_bits to the external symbols prefixed by --zprefix
 49 - Add contrib/vstudio/vc10 pre-build step for static only
 50 - Quote --version-script argument in CMakeLists.txt
 51 - Don't specify --version-script on Apple platforms in CMakeLists.txt
 52 - Fix casting error in contrib/testzlib/testzlib.c
 53 - Fix types in contrib/minizip to match result of get_crc_table()
 54 - Simplify contrib/vstudio/vc10 with 'd' suffix
 55 - Add TOP support to win32/Makefile.msc
 56 - Suport i686 and amd64 assembler builds in CMakeLists.txt
 57 - Fix typos in the use of _LARGEFILE64_SOURCE in zconf.h
 58 - Add vc11 and vc12 build files to contrib/vstudio
 59 - Add gzvprintf() as an undocumented function in zlib
 60 - Fix configure for Sun shell
```

```
 61 - Remove runtime check in configure for four-byte integer type
 62 - Add casts and consts to ease user conversion to C++
 63 - Add man pages for minizip and miniunzip
 64 - In Makefile uninstall, don't rm if preceding cd fails
 65 - Do not return Z_BUF_ERROR if deflateParam() has nothing to write

 67 Changes in 1.2.7 (2 May 2012)
 68 - Replace use of memmove() with a simple copy for portability
 69 - Test for existence of strerror
 70 - Restore gzgetc_ for backward compatibility with 1.2.6
 71 - Fix build with non-GNU make on Solaris
 72 - Require gcc 4.0 or later on Mac OS X to use the hidden attribute
 73 - Include unistd.h for Watcom C
 74 - Use __WATCOMC__ instead of __WATCOM__
 75 - Do not use the visibility attribute if NO_VIZ defined
 76 - Improve the detection of no hidden visibility attribute
 77 - Avoid using __int64 for gcc or solo compilation
 78 - Cast to char * in gzprintf to avoid warnings [Zinser]
 79 - Fix make_vms.com for VAX [Zinser]
 80 - Don't use library or built-in byte swaps
 81 - Simplify test and use of gcc hidden attribute
 82 - Fix bug in gzclose_w() when gzwrite() fails to allocate memory
 83 - Add "x" (O_EXCL) and "e" (O_CLOEXEC) modes support to gzopen()
 84 - Fix bug in test/minigzip.c for configure --solo
 85 - Fix contrib/vstudio project link errors [Mohanathas]
 86 - Add ability to choose the builder in make_vms.com [Schweda]
 87 - Add DESTDIR support to mingw32 win32/Makefile.gcc
 88 - Fix comments in win32/Makefile.gcc for proper usage
 89 - Allow overriding the default install locations for cmake
 90 - Generate and install the pkg-config file with cmake
 91 - Build both a static and a shared version of zlib with cmake
 92 - Include version symbols for cmake builds
 93 - If using cmake with MSVC, add the source directory to the includes
 94 - Remove unneeded EXTRA_CFLAGS from win32/Makefile.gcc [Truta]
 95 - Move obsolete emx makefile to old [Truta]
 96 - Allow the use of -Wundef when compiling or using zlib
 97 - Avoid the use of the -u option with mktemp
 98 - Improve inflate() documentation on the use of Z_FINISH
 99 - Recognize clang as gcc
100 - Add gzopen_w() in Windows for wide character path names
101 - Rename zconf.h in CMakeLists.txt to move it out of the way
102 - Add source directory in CMakeLists.txt for building examples
103 - Look in build directory for zlib.pc in CMakeLists.txt
104 - Remove gzflags from zlibvc.def in vc9 and vc10
105 - Fix contrib/minizip compilation in the MinGW environment
106 - Update ./configure for Solaris, support --64 [Mooney]
107 - Remove -R. from Solaris shared build (possible security issue)
108 - Avoid race condition for parallel make (-j) running example
109 - Fix type mismatch between get_crc_table() and crc_table
110 - Fix parsing of version with "-" in CMakeLists.txt [Snider, Ziegler]
111 - Fix the path to zlib.map in CMakeLists.txt
112 - Force the native libtool in Mac OS X to avoid GNU libtool [Beebe]
113 - Add instructions to win32/Makefile.gcc for shared install [Torri]

115 Changes in 1.2.6.1 (12 Feb 2012)
116 - Avoid the use of the Objective-C reserved name "id"
117 - Include io.h in gzguts.h for Microsoft compilers
118 - Fix problem with ./configure --prefix and gzgetc macro
119 - Include gz_header definition when compiling zlib solo
120 - Put gzflags() functionality back in zutil.c
121 - Avoid library header include in crc32.c for Z_SOLO
122 - Use name in GCC_CLASSIC as C compiler for coverage testing, if set
123 - Minor cleanup in contrib/minizip/zip.c [Vollant]
124 - Update make_vms.com [Zinser]
125 - Remove unnecessary gzgetc_ function
126 - Use optimized byte swap operations for Microsoft and GNU [Snyder]
```

```
- Fix minor typo in zlib.h comments [Rzesniowiecki]

Changes in 1.2.6 (29 Jan 2012)
- Update the Pascal interface in contrib/pascal
- Fix function numbers for gzgetc_ in zlibvc.def files
- Fix configure.ac for contrib/minizip [Schiffer]
- Fix large-entry detection in minizip on 64-bit systems [Schiffer]
- Have ./configure use the compiler return code for error indication
- Fix CMakeLists.txt for cross compilation [McClure]
- Fix contrib/minizip/zip.c for 64-bit architectures [Dalsnes]
- Fix compilation of contrib/minizip on FreeBSD [Marquez]
- Correct suggested usages in win32/Makefile.msc [Shachar, Horvath]
- Include io.h for Turbo C / Borland C on all platforms [Truta]
- Make version explicit in contrib/minizip/configure.ac [Bosmans]
- Avoid warning for no encryption in contrib/minizip/zip.c [Vollant]
- Minor cleanup up contrib/minizip/unzip.c [Vollant]
- Fix bug when compiling minizip with C++ [Vollant]
- Protect for long name and extra fields in contrib/minizip [Vollant]
- Avoid some warnings in contrib/minizip [Vollant]
- Add -I../.. -L../.. to CFLAGS for minizip and miniunzip
- Add missing libs to minizip linker command
- Add support for VPATH builds in contrib/minizip
- Add an --enable-demos option to contrib/minizip/configure
- Add the generation of configure.log by ./configure
- Exit when required parameters not provided to win32/Makefile.gcc
- Have gzputc return the character written instead of the argument
- Use the -m option on ldconfig for BSD systems [Tobias]
- Correct in zlib.map when deflateResetKeep was added

Changes in 1.2.5.3 (15 Jan 2012)
- Restore gzgetc function for binary compatibility
- Do not use _lseeki64 under Borland C++ [Truta]
- Update win32/Makefile.msc to build test/*.c [Truta]
- Remove old/visualc6 given CMakefile and other alternatives
- Update AS400 build files and documentation [Monnerat]
- Update win32/Makefile.gcc to build test/*.c [Truta]
- Permit stronger flushes after Z_BLOCK flushes
- Avoid extraneous empty blocks when doing empty flushes
- Permit Z_NULL arguments to deflatePending
- Allow deflatePrime() to insert bits in the middle of a stream
- Remove second empty static block for Z_PARTIAL_FLUSH
- Write out all of the available bits when using Z_BLOCK
- Insert the first two strings in the hash table after a flush

Changes in 1.2.5.2 (17 Dec 2011)
- fix ld error: unable to find version dependency 'ZLIB_1.2.5'
- use relative symlinks for shared libs
- Avoid searching past window for Z_RLE strategy
- Assure that high-water mark initialization is always applied in deflate
- Add assertions to fill_window() in deflate.c to match comments
- Update python link in README
- Correct spelling error in gzread.c
- Fix bug in gzgets() for a concatenated empty gzip stream
- Correct error in comment for gz_make()
- Change gzread() and related to ignore junk after gzip streams
- Allow gzread() and related to continue after gzclearerr()
- Allow gzrewind() and gzseek() after a premature end-of-file
- Simplify gzseek() now that raw after gzip is ignored
- Change gzgetc() to a macro for speed (~40% speedup in testing)
- Fix gzclose() to return the actual error last encountered
- Always add large file support for windows
- Include zconf.h for windows large file support
- Include zconf.h.cmakein for windows large file support
- Update zconf.h.cmakein on make distclean
- Merge vestigial vsnprintf determination from zutil.h to gzguts.h
- Clarify how gzopen() appends in zlib.h comments
```

```
- Correct documentation of gzdirect() since junk at end now ignored
- Add a transparent write mode to gzopen() when 'T' is in the mode
- Update python link in zlib man page
- Get inffixed.h and MAKEFIXED result to match
- Add a ./config --solo option to make zlib subset with no libary use
- Add undocumented inflateResetKeep() function for CAB file decoding
- Add --cover option to ./configure for gcc coverage testing
- Add #define ZLIB_CONST option to use const in the z_stream interface
- Add comment to gzdopen() in zlib.h to use dup() when using fileno()
- Note behavior of uncompress() to provide as much data as it can
- Add files in contrib/minizip to aid in building libminizip
- Split off AR options in Makefile.in and configure
- Change ON macro to Z_ARG to avoid application conflicts
- Facilitate compilation with Borland C++ for pragmas and vsnprintf
- Include io.h for Turbo C / Borland C++
- Move example.c and minigzip.c to test/
- Simplify incomplete code table filling in inflate_table()
- Remove code from inflate.c and infback.c that is impossible to execute
- Test the inflate code with full coverage
- Allow deflateSetDictionary, inflateSetDictionary at any time (in raw)
- Add deflateResetKeep and fix inflateResetKeep to retain dictionary
- Fix gzwrite.c to accommodate reduced memory zlib compilation
- Have inflate() with Z_FINISH avoid the allocation of a window
- Do not set strm->adler when doing raw inflate
- Fix gzeof() to behave just like feof() when read is not past end of file
- Fix bug in gzread.c when end-of-file is reached
- Avoid use of Z_BUF_ERROR in gz* functions except for premature EOF
- Document gzread() capability to read concurrently written files
- Remove hard-coding of resource compiler in CMakeLists.txt [Blammo]

Changes in 1.2.5.1 (10 Sep 2011)
- Update FAQ entry on shared builds (#13)
- Avoid symbolic argument to chmod in Makefile.in
- Fix bug and add consts in contrib/puff [Oberhumer]
- Update contrib/puff/zeros.raw test file to have all block types
- Add full coverage test for puff in contrib/puff/Makefile
- Fix static-only-build install in Makefile.in
- Fix bug in unzGetCurrentFileInfo() in contrib/minizip [Kuno]
- Add libz.a dependency to shared in Makefile.in for parallel builds
- Spell out "number" (instead of "nb") in zlib.h for total_in, total_out
- Replace $(...) with '...' in configure for non-bash sh [Bowler]
- Add darwin* to Darwin* and solaris* to SunOS\ 5* in configure [Groffen]
- Add solaris* to Linux* in configure to allow gcc use [Groffen]
- Add *bsd* to Linux* case in configure [Bar-Lev]
- Add inffast.obj to dependencies in win32/Makefile.msc
- Correct spelling error in deflate.h [Kohler]
- Change libzdll.a again to libz.dll.a (!) in win32/Makefile.gcc
- Add test to configure for GNU C looking for gcc in output of $cc -v
- Add zlib.pc generation to win32/Makefile.gcc [Weigelt]
- Fix bug in zlib.h for _FILE_OFFSET_BITS set and _LARGEFILE64_SOURCE not
- Add comment in zlib.h that adler32_combine with len2 < 0 makes no sense
- Make NO_DIVIDE option in adler32.c much faster (thanks to John Reiser)
- Make stronger test in zconf.h to include unistd.h for LFS
- Apply Darwin patches for 64-bit file offsets to contrib/minizip [Slack]
- Fix zlib.h LFS support when Z_PREFIX used
- Add updated as400 support (removed from old) [Monnerat]
- Avoid deflate sensitivity to volatile input data
- Avoid division in adler32_combine for NO_DIVIDE
- Clarify the use of Z_FINISH with deflateBound() amount of space
- Set binary for output file in puff.c
- Use u4 type for crc_table to avoid conversion warnings
- Apply casts in zlib.h to avoid conversion warnings
- Add OF to prototypes for adler32_combine_ and crc32_combine_ [Miller]
- Improve inflateSync() documentation to note indeterminancy
- Add deflatePending() function to return the amount of pending output
- Correct the spelling of "specification" in FAQ [Randers-Pehrson]
```

```
- Add a check in configure for stdarg.h, use for gzprintf()
- Check that pointers fit in ints when gzprint() compiled old style
- Add dummy name before $(SHAREDLIBV) in Makefile [Bar-Lev, Bowler]
- Delete line in configure that adds -L. libz.a to LDFLAGS [Weigelt]
- Add debug records in assmebler code [Londer]
- Update RFC references to use http://tools.ietf.org/html/... [Li]
- Add --archs option, use of libtool to configure for Mac OS X [Borstel]

Changes in 1.2.5 (19 Apr 2010)
- Disable visibility attribute in win32/Makefile.gcc [Bar-Lev]
- Default to libdir as sharedlibdir in configure [Nieder]
- Update copyright dates on modified source files
- Update trees.c to be able to generate modified trees.h
- Exit configure for MinGW, suggesting win32/Makefile.gcc
- Check for NULL path in gz_open [Homurlu]

Changes in 1.2.4.5 (18 Apr 2010)
- Set sharedlibdir in configure [Torok]
- Set LDFLAGS in Makefile.in [Bar-Lev]
- Avoid mkdir objs race condition in Makefile.in [Bowler]
- Add ZLIB_INTERNAL in front of internal inter-module functions and arrays
- Define ZLIB_INTERNAL to hide internal functions and arrays for GNU C
- Don't use hidden attribute when it is a warning generator (e.g. Solaris)

Changes in 1.2.4.4 (18 Apr 2010)
- Fix CROSS_PREFIX executable testing, CHOST extract, mingw* [Torok]
- Undefine _LARGEFILE64_SOURCE in zconf.h if it is zero, but not if empty
- Try to use bash or ksh regardless of functionality of /bin/sh
- Fix configure incompatibility with NetBSD sh
- Remove attempt to run under bash or ksh since have better NetBSD fix
- Fix win32/Makefile.gcc for MinGW [Bar-Lev]
- Add diagnostic messages when using CROSS_PREFIX in configure
- Added --sharedlibdir option to configure [Weigelt]
- Use hidden visibility attribute when available [Frysinger]

Changes in 1.2.4.3 (10 Apr 2010)
- Only use CROSS_PREFIX in configure for ar and ranlib if they exist
- Use CROSS_PREFIX for nm [Bar-Lev]
- Assume _LARGEFILE64_SOURCE defined is equivalent to true
- Avoid use of undefined symbols in #if with && and ||
- Make *64 prototypes in gzguts.h consistent with functions
- Add -shared load option for MinGW in configure [Bowler]
- Move z_off64_t to public interface, use instead of off64_t
- Remove ! from shell test in configure (not portable to Solaris)
- Change +0 macro tests to -0 for possibly increased portability

Changes in 1.2.4.2 (9 Apr 2010)
- Add consistent carriage returns to readme.txt's in masmx86 and masmx64
- Really provide prototypes for *64 functions when building without LFS
- Only define unlink() in minigzip.c if unistd.h not included
- Update README to point to contrib/vstudio project files
- Move projects/vc6 to old/ and remove projects/
- Include stdlib.h in minigzip.c for setmode() definition under WinCE
- Clean up assembler builds in win32/Makefile.msc [Rowe]
- Include sys/types.h for Microsoft for off_t definition
- Fix memory leak on error in gz_open()
- Symbolize nm as $NM in configure [Weigelt]
- Use TEST_LDSHARED instead of LDSHARED to link test programs [Weigelt]
- Add +0 to _FILE_OFFSET_BITS and _LFS64_LARGEFILE in case not defined
- Fix bug in gzeof() to take into account unused input data
- Avoid initialization of structures with variables in puff.c
- Updated win32/README-WIN32.txt [Rowe]

Changes in 1.2.4.1 (28 Mar 2010)
- Remove the use of [a-z] constructs for sed in configure [gentoo 310225]
- Remove $(SHAREDLIB) from LIBS in Makefile.in [Creech]
```

```
- Restore "for debugging" comment on sprintf() in gzlib.c
- Remove fdopen for MVS from gzguts.h
- Put new README-WIN32.txt in win32 [Rowe]
- Add check for shell to configure and invoke another shell if needed
- Fix big fat stinking bug in gzseek() on uncompressed files
- Remove vestigial F_OPEN64 define in zutil.h
- Set and check the value of _LARGEFILE_SOURCE and _LARGEFILE64_SOURCE
- Avoid errors on non-LFS systems when applications define LFS macros
- Set EXE to ".exe" in configure for MINGW [Kahle]
- Match crc32() in crc32.c exactly to the prototype in zlib.h [Sherrill]
- Add prefix for cross-compilation in win32/makefile.gcc [Bar-Lev]
- Add DLL install in win32/makefile.gcc [Bar-Lev]
- Allow Linux* or linux* from uname in configure [Bar-Lev]
- Allow ldconfig to be redefined in configure and Makefile.in [Bar-Lev]
- Add cross-compilation prefixes to configure [Bar-Lev]
- Match type exactly in gz_load() invocation in gzread.c
- Match type exactly of zcalloc() in zutil.c to zlib.h alloc_func
- Provide prototypes for *64 functions when building zlib without LFS
- Don't use -lc when linking shared library on MinGW
- Remove errno.h check in configure and vestigial errno code in zutil.h

Changes in 1.2.4 (14 Mar 2010)
- Fix VER3 extraction in configure for no fourth subversion
- Update zlib.3, add docs to Makefile.in to make .pdf out of it
- Add zlib.3.pdf to distribution
- Don't set error code in gzerror() if passed pointer is NULL
- Apply destination directory fixes to CMakeLists.txt [Lowman]
- Move #cmakedefine's to a new zconf.in.cmakein
- Restore zconf.h for builds that don't use configure or cmake
- Add distclean to dummy Makefile for convenience
- Update and improve INDEX, README, and FAQ
- Update CMakeLists.txt for the return of zconf.h [Lowman]
- Update contrib/vstudio/vc9 and vc10 [Vollant]
- Change libz.dll.a back to libzdll.a in win32/Makefile.gcc
- Apply license and readme changes to contrib/asm686 [Raiter]
- Check file name lengths and add -c option in minigzip.c [Li]
- Update contrib/amd64 and contrib/masmx86/ [Vollant]
- Avoid use of "eof" parameter in trees.c to not shadow library variable
- Update make_vms.com for removal of zlibdefs.h [Zinser]
- Update assembler code and vstudio projects in contrib [Vollant]
- Remove outdated assembler code contrib/masm686 and contrib/asm586
- Remove old vc7 and vc8 from contrib/vstudio
- Update win32/Makefile.msc, add ZLIB_VER_SUBREVISION [Rowe]
- Fix memory leaks in gzclose_r() and gzclose_w(), file leak in gz_open()
- Add contrib/gcc_gvmat64 for longest_match and inflate_fast [Vollant]
- Remove *64 functions from win32/zlib.def (they're not 64-bit yet)
- Fix bug in void-returning vsprintf() case in gzwrite.c
- Fix name change from inflate.h in contrib/inflate86/inffas86.c
- Check if temporary file exists before removing in make_vms.com [Zinser]
- Fix make install and uninstall for --static option
- Fix usage of _MSC_VER in gzguts.h and zutil.h [Truta]
- Update readme.txt in contrib/masmx64 and masmx86 to assemble

Changes in 1.2.3.9 (21 Feb 2010)
- Expunge gzio.c
- Move as400 build information to old
- Fix updates in contrib/minizip and contrib/vstudio
- Add const to vsnprintf test in configure to avoid warnings [Weigelt]
- Delete zconf.h (made by configure) [Weigelt]
- Change zconf.in.h to zconf.h.in per convention [Weigelt]
- Check for NULL buf in gzgets()
- Return empty string for gzgets() with len == 1 (like fgets())
- Fix description of gzgets() in zlib.h for end-of-file, NULL return
- Update minizip to 1.1 [Vollant]
- Avoid MSVC loss of data warnings in gzread.c, gzwrite.c
- Note in zlib.h that gzerror() should be used to distinguish from EOF
```

```
- Remove use of snprintf() from gzlib.c
- Fix bug in gzseek()
- Update contrib/vstudio, adding vc9 and vc10 [Kuno, Vollant]
- Fix zconf.h generation in CMakeLists.txt [Lowman]
- Improve comments in zconf.h where modified by configure

Changes in 1.2.3.8 (13 Feb 2010)
- Clean up text files (tabs, trailing whitespace, etc.) [Oberhumer]
- Use z_off64_t in gz_zero() and gz_skip() to match state->skip
- Avoid comparison problem when sizeof(int) == sizeof(z_off64_t)
- Revert to Makefile.in from 1.2.3.6 (live with the clutter)
- Fix missing error return in gzflush(), add zlib.h note
- Add *64 functions to zlib.map [Levin]
- Fix signed/unsigned comparison in gz_comp()
- Use SFLAGS when testing shared linking in configure
- Add --64 option to ./configure to use -m64 with gcc
- Fix ./configure --help to correctly name options
- Have make fail if a test fails [Levin]
- Avoid buffer overrun in contrib/masmx64/gvmat64.asm [Simpson]
- Remove assembler object files from contrib

Changes in 1.2.3.7 (24 Jan 2010)
- Always gzopen() with O_LARGEFILE if available
- Fix gzdirect() to work immediately after gzopen() or gzdopen()
- Make gzdirect() more precise when the state changes while reading
- Improve zlib.h documentation in many places
- Catch memory allocation failure in gz_open()
- Complete close operation if seek forward in gzclose_w() fails
- Return Z_ERRNO from gzclose_r() if close() fails
- Return Z_STREAM_ERROR instead of EOF for gzclose() being passed NULL
- Return zero for gzwrite() errors to match zlib.h description
- Return -1 on gzputs() error to match zlib.h description
- Add zconf.in.h to allow recovery from configure modification [Weigelt]
- Fix static library permissions in Makefile.in [Weigelt]
- Avoid warnings in configure tests that hide functionality [Weigelt]
- Add *BSD and DragonFly to Linux case in configure [gentoo 123571]
- Change libzdll.a to libz.dll.a in win32/Makefile.gcc [gentoo 288212]
- Avoid access of uninitialized data for first inflateReset2 call [Gomes]
- Keep object files in subdirectories to reduce the clutter somewhat
- Remove default Makefile and zlibdefs.h, add dummy Makefile
- Add new external functions to Z_PREFIX, remove duplicates, z_z_ -> z_
- Remove zlibdefs.h completely -- modify zconf.h instead

Changes in 1.2.3.6 (17 Jan 2010)
- Avoid void * arithmetic in gzread.c and gzwrite.c
- Make compilers happier with const char * for gz_error message
- Avoid unused parameter warning in inflate.c
- Avoid signed-unsigned comparison warning in inflate.c
- Indent #pragma's for traditional C
- Fix usage of strwinerror() in glib.c, change to gz_strwinerror()
- Correct email address in configure for system options
- Update make_vms.com and add make_vms.com to contrib/minizip [Zinser]
- Update zlib.map [Brown]
- Fix Makefile.in for Solaris 10 make of example64 and minizip64 [Torok]
- Apply various fixes to CMakeLists.txt [Lowman]
- Add checks on len in gzread() and gzwrite()
- Add error message for no more room for gzungetc()
- Remove zlib version check in gzwrite()
- Defer compression of gzprintf() result until need to
- Use snprintf() in gzdopen() if available
- Remove USE_MMAP configuration determination (only used by minigzip)
- Remove examples/pigz.c (available separately)
- Update examples/gun.c to 1.6

Changes in 1.2.3.5 (8 Jan 2010)
- Add space after #if in zutil.h for some compilers
```

```
- Fix relatively harmless bug in deflate_fast() [Exarevsky]
- Fix same problem in deflate_slow()
- Add $(SHAREDLIBV) to LIBS in Makefile.in [Brown]
- Add deflate_rle() for faster Z_RLE strategy run-length encoding
- Add deflate_huff() for faster Z_HUFFMAN_ONLY encoding
- Change name of "write" variable in inffast.c to avoid library collisions
- Fix premature EOF from gzread() in gzio.c [Brown]
- Use zlib header window size if windowBits is 0 in inflateInit2()
- Remove compressBound() call in deflate.c to avoid linking compress.o
- Replace use of errno in gz* with functions, support WinCE [Alves]
- Provide alternative to perror() in minigzip.c for WinCE [Alves]
- Don't use _vsnprintf on later versions of MSVC [Lowman]
- Add CMake build script and input file [Lowman]
- Update contrib/minizip to 1.1 [Svensson, Vollant]
- Moved nintendods directory from contrib to .
- Replace gzio.c with a new set of routines with the same functionality
- Add gzbuffer(), gzoffset(), gzclose_r(), gzclose_w() as part of above
- Update contrib/minizip to 1.1b
- Change gzeof() to return 0 on error instead of -1 to agree with zlib.h

Changes in 1.2.3.4 (21 Dec 2009)
- Use old school .SUFFIXES in Makefile.in for FreeBSD compatibility
- Update comments in configure and Makefile.in for default --shared
- Fix test -z's in configure [Marquess]
- Build examplesh and minigzipsh when not testing
- Change NULL's to Z_NULL's in deflate.c and in comments in zlib.h
- Import LDFLAGS from the environment in configure
- Fix configure to populate SFLAGS with discovered CFLAGS options
- Adapt make_vms.com to the new Makefile.in [Zinser]
- Add zlib2ansi script for C++ compilation [Marquess]
- Add _FILE_OFFSET_BITS=64 test to make test (when applicable)
- Add AMD64 assembler code for longest match to contrib [Teterin]
- Include options from $SFLAGS when doing $LDSHARED
- Simplify 64-bit file support by introducing z_off64_t type
- Make shared object files in objs directory to work around old Sun cc
- Use only three-part version number for Darwin shared compiles
- Add rc option to ar in Makefile.in for when ./configure not run
- Add -WI,-rpath,. to LDFLAGS for OSF 1 V4*
- Set LD_LIBRARYN32_PATH for SGI IRIX shared compile
- Protect against _FILE_OFFSET_BITS being defined when compiling zlib
- Rename Makefile.in targets allstatic to static and allshared to shared
- Fix static and shared Makefile.in targets to be independent
- Correct error return bug in gz_open() by setting state [Brown]
- Put spaces before ;;'s in configure for better sh compatibility
- Add pigz.c (parallel implementation of gzip) to examples/
- Correct constant in crc32.c to UL [Leventhal]
- Reject negative lengths in crc32_combine()
- Add inflateReset2() function to work like inflateEnd()/inflateInit2()
- Include sys/types.h for _LARGEFILE64_SOURCE [Brown]
- Correct typo in doc/algorithm.txt [Janik]
- Fix bug in adler32_combine() [Zhu]
- Catch missing-end-of-block-code error in all inflates and in puff
    Assures that random input to inflate eventually results in an error
- Added enough.c (calculation of ENOUGH for inftrees.h) to examples/
- Update ENOUGH and its usage to reflect discovered bounds
- Fix gzerror() error report on empty input file [Brown]
- Add ush casts in trees.c to avoid pedantic runtime errors
- Fix typo in zlib.h uncompress() description [Reiss]
- Correct inflate() comments with regard to automatic header detection
- Remove deprecation comment on Z_PARTIAL_FLUSH (it stays)
- Put new version of gzlog (2.0) in examples with interruption recovery
- Add puff compile option to permit invalid distance-too-far streams
- Add puff TEST command options, ability to read piped input
- Prototype the *64 functions in zlib.h when _FILE_OFFSET_BITS == 64, but
  _LARGEFILE64_SOURCE not defined
- Fix Z_FULL_FLUSH to truly erase the past by resetting s->strstart
```

- Fix deflateSetDictionary() to use all 32K for output consistency
- Remove extraneous #define MIN_LOOKAHEAD in deflate.c (in deflate.h)
- Clear bytes after deflate lookahead to avoid use of uninitialized data
- Change a limit in inftrees.c to be more transparent to Coverity Prevent
- Update win32/zlib.def with exported symbols from zlib.h
- Correct spelling errors in zlib.h [Willem, Sobrado]
- Allow Z_BLOCK for deflate() to force a new block
- Allow negative bits in inflatePrime() to delete existing bit buffer
- Add Z_TREES flush option to inflate() to return at end of trees
- Add inflateMark() to return current state information for random access
- Add Makefile for NintendoDS to contrib [Costa]
- Add -w in configure compile tests to avoid spurious warnings [Beucler]
- Fix typos in zlib.h comments for deflateSetDictionary()
- Fix EOF detection in transparent gzread() [Maier]

Changes in 1.2.3.3 (2 October 2006)
- Make --shared the default for configure, add a --static option
- Add compile option to permit invalid distance-too-far streams
- Add inflateUndermine() function which is required to enable above
- Remove use of "this" variable name for C++ compatibility [Marquess]
- Add testing of shared library in make test, if shared library built
- Use ftello() and fseeko() if available instead of ftell() and fseek()
- Provide two versions of all functions that use the z_off_t type for
  binary compatibility -- a normal version and a 64-bit offset version,
  per the Large File Support Extension when _LARGEFILE64_SOURCE is
  defined; use the 64-bit versions by default when _FILE_OFFSET_BITS
  is defined to be 64
- Add a --uname= option to configure to perhaps help with cross-compiling

Changes in 1.2.3.2 (3 September 2006)
- Turn off silly Borland warnings [Hay]
- Use off64_t and define _LARGEFILE64_SOURCE when present
- Fix missing dependency on inffixed.h in Makefile.in
- Rig configure --shared to build both shared and static [Teredesai, Truta]
- Remove zconf.in.h and instead create a new zlibdefs.h file
- Fix contrib/minizip/unzip.c non-encrypted after encrypted [Vollant]
- Add treebuild.xml (see http://treebuild.metux.de/) [Weigelt]

Changes in 1.2.3.1 (16 August 2006)
- Add watcom directory with OpenWatcom make files [Daniel]
- Remove #undef of FAR in zconf.in.h for MVS [Fedtke]
- Update make_vms.com [Zinser]
- Use -fPIC for shared build in configure [Teredesai, Nicholson]
- Use only major version number for libz.so on IRIX and OSF1 [Reinholdtsen]
- Use fdopen() (not _fdopen()) for Interix in zutil.h [B´ ck]
- Add some FAQ entries about the contrib directory
- Update the MVS question in the FAQ
- Avoid extraneous reads after EOF in gzio.c [Brown]
- Correct spelling of "successfully" in gzio.c [Randers-Pehrson]
- Add comments to zlib.h about gzerror() usage [Brown]
- Set extra flags in gzip header in gzopen() like deflate() does
- Make configure options more compatible with double-dash conventions
  [Weigelt]
- Clean up compilation under Solaris SunStudio cc [Rowe, Reinholdtsen]
- Fix uninstall target in Makefile.in [Truta]
- Add pkgconfig support [Weigelt]
- Use $(DESTDIR) macro in Makefile.in [Reinholdtsen, Weigelt]
- Replace set_data_type() with a more accurate detect_data_type() in
  trees.c, according to the txtvsbin.txt document [Truta]
- Swap the order of #include <stdio.h> and #include "zlib.h" in
  gzio.c, example.c and minigzip.c [Truta]
- Shut up annoying VS2005 warnings about standard C deprecation [Rowe,
  Truta] (where?)
- Fix target "clean" from win32/Makefile.bor [Truta]
- Create .pdb and .manifest files in win32/makefile.msc [Ziegler, Rowe]
- Update zlib www home address in win32/DLL_FAQ.txt [Truta]

- Update contrib/masmx86/inffas32.asm for VS2005 [Vollant, Van Wassenhove]
- Enable browse info in the "Debug" and "ASM Debug" configurations in
  the Visual C++ 6 project, and set (non-ASM) "Debug" as default [Truta]
- Add pkgconfig support [Weigelt]
- Add ZLIB_VER_MAJOR, ZLIB_VER_MINOR and ZLIB_VER_REVISION in zlib.h,
  for use in win32/zlib1.rc [Polushin, Rowe, Truta]
- Add a document that explains the new text detection scheme to
  doc/txtvsbin.txt [Truta]
- Add rfc1950.txt, rfc1951.txt and rfc1952.txt to doc/ [Truta]
- Move algorithm.txt into doc/ [Truta]
- Synchronize FAQ with website
- Fix compressBound(), was low for some pathological cases [Fearnley]
- Take into account wrapper variations in deflateBound()
- Set examples/zpipe.c input and output to binary mode for Windows
- Update examples/zlib_how.html with new zpipe.c (also web site)
- Fix some warnings in examples/gzlog.c and examples/zran.c (it seems
  that gcc became pickier in 4.0)
- Add zlib.map for Linux: "All symbols from zlib-1.1.4 remain
  un-versioned, the patch adds versioning only for symbols introduced in
  zlib-1.2.0 or later. It also declares as local those symbols which are
  not designed to be exported." [Levin]
- Update Z_PREFIX list in zconf.in.h, add --zprefix option to configure
- Do not initialize global static by default in trees.c, add a response
  NO_INIT_GLOBAL_POINTERS to initialize them if needed [Marquess]
- Don’t use strerror() in gzio.c under WinCE [Yakimov]
- Don’t use errno.h in zutil.h under WinCE [Yakimov]
- Move arguments for AR to its usage to allow replacing ar [Marot]
- Add HAVE_VISIBILITY_PRAGMA in zconf.in.h for Mozilla [Randers-Pehrson]
- Improve inflateInit() and inflateInit2() documentation
- Fix structure size comment in inflate.h
- Change configure help option from --h* to --help [Santos]

Changes in 1.2.3 (18 July 2005)
- Apply security vulnerability fixes to contrib/infback9 as well
- Clean up some text files (carriage returns, trailing space)
- Update testzlib, vstudio, masmx64, and masmx86 in contrib [Vollant]

Changes in 1.2.2.4 (11 July 2005)
- Add inflatePrime() function for starting inflation at bit boundary
- Avoid some Visual C warnings in deflate.c
- Avoid more silly Visual C warnings in inflate.c and inftrees.c for 64-bit
  compile
- Fix some spelling errors in comments [Betts]
- Correct inflateInit2() error return documentation in zlib.h
- Add zran.c example of compressed data random access to examples
  directory, shows use of inflatePrime()
- Fix cast for assignments to strm->state in inflate.c and infback.c
- Fix zlibCompileFlags() in zutil.c to use 1L for long shifts [Oberhumer]
- Move declarations of gf2 functions to right place in crc32.c [Oberhumer]
- Add cast in trees.c t avoid a warning [Oberhumer]
- Avoid some warnings in fitblk.c, gun.c, gzjoin.c in examples [Oberhumer]
- Update make_vms.com [Zinser]
- Initialize state->write in inflateReset() since copied in inflate_fast()
- Be more strict on incomplete code sets in inflate_table() and increase
  ENOUGH and MAXD -- this repairs a possible security vulnerability for
  invalid inflate input. Thanks to Tavis Ormandy and Markus Oberhumer for
  discovering the vulnerability and providing test cases.
- Add ia64 support to configure for HP-UX [Smith]
- Add error return to gzread() for format or i/o error [Levin]
- Use malloc.h for OS/2 [Necasek]

Changes in 1.2.2.3 (27 May 2005)
- Replace 1U constants in inflate.c and inftrees.c for 64-bit compile
- Typecast fread() return values in gzio.c [Vollant]
- Remove trailing space in minigzip.c outmode (VC++ can’t deal with it)
- Fix crc check bug in gzread() after gzungetc() [Heiner]

```
- Add the deflateTune() function to adjust internal compression parameters
- Add a fast gzip decompressor, gun.c, to examples (use of inflateBack)
- Remove an incorrect assertion in examples/zpipe.c
- Add C++ wrapper in infback9.h [Donais]
- Fix bug in inflateCopy() when decoding fixed codes
- Note in zlib.h how much deflateSetDictionary() actually uses
- Remove USE_DICT_HEAD in deflate.c (would mess up inflate if used)
- Add _WIN32_WCE to define WIN32 in zconf.in.h [Spencer]
- Don't include stderr.h or errno.h for _WIN32_WCE in zutil.h [Spencer]
- Add gzdirect() function to indicate transparent reads
- Update contrib/minizip [Vollant]
- Fix compilation of deflate.c when both ASMV and FASTEST [Oberhumer]
- Add casts in crc32.c to avoid warnings [Oberhumer]
- Add contrib/masmx64 [Vollant]
- Update contrib/asm586, asm686, masmx86, testzlib, vstudio [Vollant]

Changes in 1.2.2.2 (30 December 2004)
- Replace structure assignments in deflate.c and inflate.c with zmemcpy to
  avoid implicit memcpy calls (portability for no-library compilation)
- Increase sprintf() buffer size in gzdopen() to allow for large numbers
- Add INFLATE_STRICT to check distances against zlib header
- Improve WinCE errno handling and comments [Chang]
- Remove comment about no gzip header processing in FAQ
- Add Z_FIXED strategy option to deflateInit2() to force fixed trees
- Add updated make_vms.com [Coghlan], update README
- Create a new "examples" directory, move gzappend.c there, add zpipe.c,
  fitblk.c, gzlog.[ch], gzjoin.c, and zlib_how.html.
- Add FAQ entry and comments in deflate.c on uninitialized memory access
- Add Solaris 9 make options in configure [Gilbert]
- Allow strerror() usage in gzio.c for STDC
- Fix DecompressBuf in contrib/delphi/ZLib.pas [ManChesTer]
- Update contrib/masmx86/inffas32.asm and gvmat32.asm [Vollant]
- Use z_off_t for adler32_combine() and crc32_combine() lengths
- Make adler32() much faster for small len
- Use OS_CODE in deflate() default gzip header

Changes in 1.2.2.1 (31 October 2004)
- Allow inflateSetDictionary() call for raw inflate
- Fix inflate header crc check bug for file names and comments
- Add deflateSetHeader() and gz_header structure for custom gzip headers
- Add inflateGetheader() to retrieve gzip headers
- Add crc32_combine() and adler32_combine() functions
- Add alloc_func, free_func, in_func, out_func to Z_PREFIX list
- Use zstreamp consistently in zlib.h (inflate_back functions)
- Remove GUNZIP condition from definition of inflate_mode in inflate.h
  and in contrib/inflate86/inffast.S [Truta, Anderson]
- Add support for AMD64 in contrib/inflate86/inffas86.c [Anderson]
- Update projects/README.projects and projects/visualc6 [Truta]
- Update win32/DLL_FAQ.txt [Truta]
- Avoid warning under NO_GZCOMPRESS in gzio.c; fix typo [Truta]
- Deprecate Z_ASCII; use Z_TEXT instead [Truta]
- Use a new algorithm for setting strm->data_type in trees.c [Truta]
- Do not define an exit() prototype in zutil.c unless DEBUG defined
- Remove prototype of exit() from zutil.c, example.c, minigzip.c [Truta]
- Add comment in zlib.h for Z_NO_FLUSH parameter to deflate()
- Fix Darwin build version identification [Peterson]

Changes in 1.2.2 (3 October 2004)
- Update zlib.h comments on gzip in-memory processing
- Set adler to 1 in inflateReset() to support Java test suite [Walles]
- Add contrib/dotzlib [Ravn]
- Update win32/DLL_FAQ.txt [Truta]
- Update contrib/minizip [Vollant]
- Move contrib/visual-basic.txt to old/ [Truta]
- Fix assembler builds in projects/visualc6/ [Truta]
```

```
Changes in 1.2.1.2 (9 September 2004)
- Update INDEX file
- Fix trees.c to update strm->data_type (no one ever noticed!)
- Fix bug in error case in inflate.c, infback.c, and infback9.c [Brown]
- Add "volatile" to crc table flag declaration (for DYNAMIC_CRC_TABLE)
- Add limited multitasking protection to DYNAMIC_CRC_TABLE
- Add NO_vsnprintf for VMS in zutil.h [Mozilla]
- Don't declare strerror() under VMS [Mozilla]
- Add comment to DYNAMIC_CRC_TABLE to use get_crc_table() to initialize
- Update contrib/ada [Anisimkov]
- Update contrib/minizip [Vollant]
- Fix configure to not hardcode directories for Darwin [Peterson]
- Fix gzio.c to not return error on empty files [Brown]
- Fix indentation; update version in contrib/delphi/ZLib.pas and
  contrib/pascal/zlibpas.pas [Truta]
- Update mkasm.bat in contrib/masmx86 [Truta]
- Update contrib/untgz [Truta]
- Add projects/README.projects [Truta]
- Add project for MS Visual C++ 6.0 in projects/visualc6 [Cadieux, Truta]
- Update win32/DLL_FAQ.txt [Truta]
- Update list of Z_PREFIX symbols in zconf.h [Randers-Pehrson, Truta]
- Remove an unnecessary assignment to curr in inftrees.c [Truta]
- Add OS/2 to exe builds in configure [Poltorak]
- Remove err dummy parameter in zlib.h [Kientzle]

Changes in 1.2.1.1 (9 January 2004)
- Update email address in README
- Several FAQ updates
- Fix a big fat bug in inftrees.c that prevented decoding valid
  dynamic blocks with only literals and no distance codes --
  Thanks to "Hot Emu" for the bug report and sample file
- Add a note to puff.c on no distance codes case.

Changes in 1.2.1 (17 November 2003)
- Remove a tab in contrib/gzappend/gzappend.c
- Update some interfaces in contrib for new zlib functions
- Update zlib version number in some contrib entries
- Add Windows CE definition for ptrdiff_t in zutil.h [Mai, Truta]
- Support shared libraries on Hurd and KFreeBSD [Brown]
- Fix error in NO_DIVIDE option of adler32.c

Changes in 1.2.0.8 (4 November 2003)
- Update version in contrib/delphi/ZLib.pas and contrib/pascal/zlibpas.pas
- Add experimental NO_DIVIDE #define in adler32.c
    - Possibly faster on some processors (let me know if it is)
- Correct Z_BLOCK to not return on first inflate call if no wrap
- Fix strm->data_type on inflate() return to correctly indicate EOB
- Add deflatePrime() function for appending in the middle of a byte
- Add contrib/gzappend for an example of appending to a stream
- Update win32/DLL_FAQ.txt [Truta]
- Delete Turbo C comment in README [Truta]
- Improve some indentation in zconf.h [Truta]
- Fix infinite loop on bad input in configure script [Church]
- Fix gzeof() for concatenated gzip files [Johnson]
- Add example to contrib/visual-basic.txt [Michael B.]
- Add -p to mkdir's in Makefile.in [vda]
- Fix configure to properly detect presence or lack of printf functions
- Add AS400 support [Monnerat]
- Add a little Cygwin support [Wilson]

Changes in 1.2.0.7 (21 September 2003)
- Correct some debug formats in contrib/infback9
- Cast a type in a debug statement in trees.c
- Change search and replace delimiter in configure from % to # [Beebe]
- Update contrib/untgz to 0.2 with various fixes [Truta]
- Add build support for Amiga [Nikl]
```

```
- Remove some directories in old that have been updated to 1.2
- Add dylib building for Mac OS X in configure and Makefile.in
- Remove old distribution stuff from Makefile
- Update README to point to DLL_FAQ.txt, and add comment on Mac OS X
- Update links in README

Changes in 1.2.0.6 (13 September 2003)
- Minor FAQ updates
- Update contrib/minizip to 1.00 [Vollant]
- Remove test of gz functions in example.c when GZ_COMPRESS defined [Truta]
- Update POSTINC comment for 68060 [Nikl]
- Add contrib/infback9 with deflate64 decoding (unsupported)
- For MVS define NO_vsnprintf and undefine FAR [van Burik]
- Add pragma for fdopen on MVS [van Burik]

Changes in 1.2.0.5 (8 September 2003)
- Add OF to inflateBackEnd() declaration in zlib.h
- Remember start when using gzdopen in the middle of a file
- Use internal off_t counters in gz* functions to properly handle seeks
- Perform more rigorous check for distance-too-far in inffast.c
- Add Z_BLOCK flush option to return from inflate at block boundary
- Set strm->data_type on return from inflate
    - Indicate bits unused, if at block boundary, and if in last block
- Replace size_t with ptrdiff_t in crc32.c, and check for correct size
- Add condition so old NO_DEFLATE define still works for compatibility
- FAQ update regarding the Windows DLL [Truta]
- INDEX update: add qnx entry, remove aix entry [Truta]
- Install zlib.3 into mandir [Wilson]
- Move contrib/zlib_dll_FAQ.txt to win32/DLL_FAQ.txt; update [Truta]
- Adapt the zlib interface to the new DLL convention guidelines [Truta]
- Introduce ZLIB_WINAPI macro to allow the export of functions using
  the WINAPI calling convention, for Visual Basic [Vollant, Truta]
- Update msdos and win32 scripts and makefiles [Truta]
- Export symbols by name, not by ordinal, in win32/zlib.def [Truta]
- Add contrib/ada [Anisimkov]
- Move asm files from contrib/vstudio/vc70_32 to contrib/asm386 [Truta]
- Rename contrib/asm386 to contrib/masmx86 [Truta, Vollant]
- Add contrib/masm686 [Truta]
- Fix offsets in contrib/inflate86 and contrib/masmx86/inffas32.asm
  [Truta, Vollant]
- Update contrib/delphi; rename to contrib/pascal; add example [Truta]
- Remove contrib/delphi2; add a new contrib/delphi [Truta]
- Avoid inclusion of the nonstandard <memory.h> in contrib/iostream,
  and fix some method prototypes [Truta]
- Fix the ZCR_SEED2 constant to avoid warnings in contrib/minizip
  [Truta]
- Avoid the use of backslash (\) in contrib/minizip [Vollant]
- Fix file time handling in contrib/untgz; update makefiles [Truta]
- Update contrib/vstudio/vc70_32 to comply with the new DLL guidelines
  [Vollant]
- Remove contrib/vstudio/vc15_16 [Vollant]
- Rename contrib/vstudio/vc70_32 to contrib/vstudio/vc7 [Truta]
- Update README.contrib [Truta]
- Invert the assignment order of match_head and s->prev[...] in
  INSERT_STRING [Truta]
- Compare TOO_FAR with 32767 instead of 32768, to avoid 16-bit warnings
  [Truta]
- Compare function pointers with 0, not with NULL or Z_NULL [Truta]
- Fix prototype of syncsearch in inflate.c [Truta]
- Introduce ASMINF macro to be enabled when using an ASM implementation
  of inflate_fast [Truta]
- Change NO_DEFLATE to NO_GZCOMPRESS [Truta]
- Modify test_gzio in example.c to take a single file name as a
  parameter [Truta]
- Exit the example.c program if gzopen fails [Truta]
- Add type casts around strlen in example.c [Truta]
```

```
- Remove casting to sizeof in minigzip.c; give a proper type
  to the variable compared with SUFFIX_LEN [Truta]
- Update definitions of STDC and STDC99 in zconf.h [Truta]
- Synchronize zconf.h with the new Windows DLL interface [Truta]
- Use SYS16BIT instead of __32BIT__ to distinguish between
  16- and 32-bit platforms [Truta]
- Use far memory allocators in small 16-bit memory models for
  Turbo C [Truta]
- Add info about the use of ASMV, ASMINF and ZLIB_WINAPI in
  zlibCompileFlags [Truta]
- Cygwin has vsnprintf [Wilson]
- In Windows16, OS_CODE is 0, as in MSDOS [Truta]
- In Cygwin, OS_CODE is 3 (Unix), not 11 (Windows32) [Wilson]

Changes in 1.2.0.4 (10 August 2003)
- Minor FAQ updates
- Be more strict when checking inflateInit2's windowBits parameter
- Change NO_GUNZIP compile option to NO_GZIP to cover deflate as well
- Add gzip wrapper option to deflateInit2 using windowBits
- Add updated QNX rule in configure and qnx directory [Bonnefoy]
- Make inflate distance-too-far checks more rigorous
- Clean up FAR usage in inflate
- Add casting to sizeof() in gzio.c and minigzip.c

Changes in 1.2.0.3 (19 July 2003)
- Fix silly error in gzungetc() implementation [Vollant]
- Update contrib/minizip and contrib/vstudio [Vollant]
- Fix printf format in example.c
- Correct cdecl support in zconf.in.h [Anisimkov]
- Minor FAQ updates

Changes in 1.2.0.2 (13 July 2003)
- Add ZLIB_VERNUM in zlib.h for numerical preprocessor comparisons
- Attempt to avoid warnings in crc32.c for pointer-int conversion
- Add AIX to configure, remove aix directory [Bakker]
- Add some casts to minigzip.c
- Improve checking after insecure sprintf() or vsprintf() calls
- Remove #elif's from crc32.c
- Change leave label to inf_leave in inflate.c and infback.c to avoid
  library conflicts
- Remove inflate gzip decoding by default--only enable gzip decoding by
  special request for stricter backward compatibility
- Add zlibCompileFlags() function to return compilation information
- More typecasting in deflate.c to avoid warnings
- Remove leading underscore from _Capital #defines [Truta]
- Fix configure to link shared library when testing
- Add some Windows CE target adjustments [Mai]
- Remove #define ZLIB_DLL in zconf.h [Vollant]
- Add zlib.3 [Rodgers]
- Update RFC URL in deflate.c and algorithm.txt [Mai]
- Add zlib_dll_FAQ.txt to contrib [Truta]
- Add UL to some constants [Truta]
- Update minizip and vstudio [Vollant]
- Remove vestigial NEED_DUMMY_RETURN from zconf.in.h
- Expand use of NO_DUMMY_DECL to avoid all dummy structures
- Added iostream3 to contrib [Schwardt]
- Replace rewind() with fseek() for WinCE [Truta]
- Improve setting of zlib format compression level flags
    - Report 0 for huffman and rle strategies and for level == 0 or 1
    - Report 2 only for level == 6
- Only deal with 64K limit when necessary at compile time [Truta]
- Allow TOO_FAR check to be turned off at compile time [Truta]
- Add gzclearerr() function [Souza]
- Add gzungetc() function

Changes in 1.2.0.1 (17 March 2003)
```

```
- Add Z_RLE strategy for run-length encoding [Truta]
   - When Z_RLE requested, restrict matches to distance one
   - Update zlib.h, minigzip.c, gzopen(), gzdopen() for Z_RLE
- Correct FASTEST compilation to allow level == 0
- Clean up what gets compiled for FASTEST
- Incorporate changes to zconf.in.h [Vollant]
   - Refine detection of Turbo C need for dummy returns
   - Refine ZLIB_DLL compilation
   - Include additional header file on VMS for off_t typedef
- Try to use _vsnprintf where it supplants vsprintf [Vollant]
- Add some casts in inffast.c
- Enchance comments in zlib.h on what happens if gzprintf() tries to
  write more than 4095 bytes before compression
- Remove unused state from inflateBackEnd()
- Remove exit(0) from minigzip.c, example.c
- Get rid of all those darn tabs
- Add "check" target to Makefile.in that does the same thing as "test"
- Add "mostlyclean" and "maintainer-clean" targets to Makefile.in
- Update contrib/inflate86 [Anderson]
- Update contrib/testzlib, contrib/vstudio, contrib/minizip [Vollant]
- Add msdos and win32 directories with makefiles [Truta]
- More additions and improvements to the FAQ

Changes in 1.2.0 (9 March 2003)
- New and improved inflate code
   - About 20% faster
   - Does not allocate 32K window unless and until needed
   - Automatically detects and decompresses gzip streams
   - Raw inflate no longer needs an extra dummy byte at end
   - Added inflateBack functions using a callback interface--even faster
     than inflate, useful for file utilities (gzip, zip)
   - Added inflateCopy() function to record state for random access on
     externally generated deflate streams (e.g. in gzip files)
   - More readable code (I hope)
- New and improved crc32()
   - About 50% faster, thanks to suggestions from Rodney Brown
- Add deflateBound() and compressBound() functions
- Fix memory leak in deflateInit2()
- Permit setting dictionary for raw deflate (for parallel deflate)
- Fix const declaration for gzwrite()
- Check for some malloc() failures in gzio.c
- Fix bug in gzopen() on single-byte file 0x1f
- Fix bug in gzread() on concatenated file with 0x1f at end of buffer
  and next buffer doesn't start with 0x8b
- Fix uncompress() to return Z_DATA_ERROR on truncated input
- Free memory at end of example.c
- Remove MAX #define in trees.c (conflicted with some libraries)
- Fix static const's in deflate.c, gzio.c, and zutil.[ch]
- Declare malloc() and free() in gzio.c if STDC not defined
- Use malloc() instead of calloc() in zutil.c if int big enough
- Define STDC for AIX
- Add aix/ with approach for compiling shared library on AIX
- Add HP-UX support for shared libraries in configure
- Add OpenUNIX support for shared libraries in configure
- Use $cc instead of gcc to build shared library
- Make prefix directory if needed when installing
- Correct Macintosh avoidance of typedef Byte in zconf.h
- Correct Turbo C memory allocation when under Linux
- Use libz.a instead of -lz in Makefile (assure use of compiled library)
- Update configure to check for snprintf or vsnprintf functions and their
  return value, warn during make if using an insecure function
- Fix configure problem with compile-time knowledge of HAVE_UNISTD_H that
  is lost when library is used--resolution is to build new zconf.h
- Documentation improvements (in zlib.h):
   - Document raw deflate and inflate
   - Update RFCs URL
```

```
   - Point out that zlib and gzip formats are different
   - Note that Z_BUF_ERROR is not fatal
   - Document string limit for gzprintf() and possible buffer overflow
   - Note requirement on avail_out when flushing
   - Note permitted values of flush parameter of inflate()
- Add some FAQs (and even answers) to the FAQ
- Add contrib/inflate86/ for x86 faster inflate
- Add contrib/blast/ for PKWare Data Compression Library decompression
- Add contrib/puff/ simple inflate for deflate format description

Changes in 1.1.4 (11 March 2002)
- ZFREE was repeated on same allocation on some error conditions.
  This creates a security problem described in
  http://www.zlib.org/advisory-2002-03-11.txt
- Returned incorrect error (Z_MEM_ERROR) on some invalid data
- Avoid accesses before window for invalid distances with inflate window
  less than 32K.
- force windowBits > 8 to avoid a bug in the encoder for a window size
  of 256 bytes. (A complete fix will be available in 1.1.5).

Changes in 1.1.3 (9 July 1998)
- fix "an inflate input buffer bug that shows up on rare but persistent
  occasions" (Mark)
- fix gzread and gztell for concatenated .gz files (Didier Le Botlan)
- fix gzseek(..., SEEK_SET) in write mode
- fix crc check after a gzeek (Frank Faubert)
- fix miniunzip when the last entry in a zip file is itself a zip file
  (J Lillge)
- add contrib/asm586 and contrib/asm686 (Brian Raiter)
  See http://www.muppetlabs.com/~breadbox/software/assembly.html
- add support for Delphi 3 in contrib/delphi (Bob Dellaca)
- add support for C++Builder 3 and Delphi 3 in contrib/delphi2 (Davide Moretti)
- do not exit prematurely in untgz if 0 at start of block (Magnus Holmgren)
- use macro EXTERN instead of extern to support DLL for BeOS (Sander Stoks)
- added a FAQ file

- Support gzdopen on Mac with Metrowerks (Jason Linhart)
- Do not redefine Byte on Mac (Brad Pettit & Jason Linhart)
- define SEEK_END too if SEEK_SET is not defined (Albert Chin-A-Young)
- avoid some warnings with Borland C (Tom Tanner)
- fix a problem in contrib/minizip/zip.c for 16-bit MSDOS (Gilles Vollant)
- emulate utime() for WIN32 in contrib/untgz  (Gilles Vollant)
- allow several arguments to configure (Tim Mooney, Frodo Looijaard)
- use libdir and includedir in Makefile.in (Tim Mooney)
- support shared libraries on OSF1 V4 (Tim Mooney)
- remove so_locations in "make clean"  (Tim Mooney)
- fix maketree.c compilation error (Glenn, Mark)
- Python interface to zlib now in Python 1.5 (Jeremy Hylton)
- new Makefile.riscos (Rich Walker)
- initialize static descriptors in trees.c for embedded targets (Nick Smith)
- use "foo-gz" in example.c for RISCOS and VMS (Nick Smith)
- add the OS/2 files in Makefile.in too (Andrew Zabolotny)
- fix fdopen and halloc macros for Microsoft C 6.0 (Tom Lane)
- fix maketree.c to allow clean compilation of inffixed.h (Mark)
- fix parameter check in deflateCopy (Gunther Nikl)
- cleanup trees.c, use compressed_len only in debug mode (Christian Spieler)
- Many portability patches by Christian Spieler:
  . zutil.c, zutil.h: added "const" for zmem*
  . Make_vms.com: fixed some typos
  . Make_vms.com: msdos/Makefile.*: removed zutil.h from some dependency lists
  . msdos/Makefile.msc: remove "default rtl link library" info from obj files
  . msdos/Makefile.*: use model-dependent name for the built zlib library
  . msdos/Makefile.emx, nt/Makefile.emx, nt/Makefile.gcc:
    new makefiles, for emx (DOS/OS2), emx&rsxnt and mingw32 (Windows 9x / NT)
- use define instead of typedef for Bytef also for MSC small/medium (Tom Lane)
- replace __far with _far for better portability (Christian Spieler, Tom Lane)
```

```
- fix test for errno.h in configure (Tim Newsham)

Changes in 1.1.2 (19 March 98)
- added contrib/minzip, mini zip and unzip based on zlib (Gilles Vollant)
  See http://www.winimage.com/zLibDll/unzip.html
- preinitialize the inflate tables for fixed codes, to make the code
  completely thread safe (Mark)
- some simplifications and slight speed-up to the inflate code (Mark)
- fix gzeof on non-compressed files (Allan Schrum)
- add -std1 option in configure for OSF1 to fix gzprintf (Martin Mokrejs)
- use default value of 4K for Z_BUFSIZE for 16-bit MSDOS (Tim Wegner + Glenn)
- added os2/Makefile.def and os2/zlib.def (Andrew Zabolotny)
- add shared lib support for UNIX_SV4.2MP (MATSUURA Takanori)
- do not wrap extern "C" around system includes (Tom Lane)
- mention zlib binding for TCL in README (Andreas Kupries)
- added amiga/Makefile.pup for Amiga powerUP SAS/C PPC (Andreas Kleinert)
- allow "make install prefix=..." even after configure (Glenn Randers-Pehrson)
- allow "configure --prefix $HOME" (Tim Mooney)
- remove warnings in example.c and gzio.c (Glenn Randers-Pehrson)
- move Makefile.sas to amiga/Makefile.sas

Changes in 1.1.1 (27 Feb 98)
- fix macros _tr_tally_* in deflate.h for debug mode  (Glenn Randers-Pehrson)
- remove block truncation heuristic which had very marginal effect for zlib
  (smaller lit_bufsize than in gzip 1.2.4) and degraded a little the
  compression ratio on some files. This also allows inlining _tr_tally for
  matches in deflate_slow.
- added msdos/Makefile.w32 for WIN32 Microsoft Visual C++ (Bob Frazier)

Changes in 1.1.0 (24 Feb 98)
- do not return STREAM_END prematurely in inflate (John Bowler)
- revert to the zlib 1.0.8 inflate to avoid the gcc 2.8.0 bug (Jeremy Buhler)
- compile with -DFASTEST to get compression code optimized for speed only
- in minigzip, try mmap'ing the input file first (Miguel Albrecht)
- increase size of I/O buffers in minigzip.c and gzio.c (not a big gain
  on Sun but significant on HP)

- add a pointer to experimental unzip library in README (Gilles Vollant)
- initialize variable gcc in configure (Chris Herborth)

Changes in 1.0.9 (17 Feb 1998)
- added gzputs and gzgets functions
- do not clear eof flag in gzseek (Mark Diekhans)
- fix gzseek for files in transparent mode (Mark Diekhans)
- do not assume that vsprintf returns the number of bytes written (Jens Krinke)
- replace EXPORT with ZEXPORT to avoid conflict with other programs
- added compress2 in zconf.h, zlib.def, zlib.dnt
- new asm code from Gilles Vollant in contrib/asm386
- simplify the inflate code (Mark):
 . Replace ZALLOC's in huft_build() with single ZALLOC in inflate_blocks_new()
 . ZALLOC the length list in inflate_trees_fixed() instead of using stack
 . ZALLOC the value area for huft_build() instead of using stack
 . Simplify Z_FINISH check in inflate()

- Avoid gcc 2.8.0 comparison bug a little differently than zlib 1.0.8
- in inftrees.c, avoid cc -O bug on HP (Farshid Elahi)
- in zconf.h move the ZLIB_DLL stuff earlier to avoid problems with
  the declaration of FAR (Gilles VOllant)
- install libz.so* with mode 755 (executable) instead of 644 (Marc Lehmann)
- read_buf buf parameter of type Bytef* instead of charf*
- zmemcpy parameters are of type Bytef*, not charf* (Joseph Strout)
- do not redeclare unlink in minigzip.c for WIN32 (John Bowler)
- fix check for presence of directories in "make install" (Ian Willis)

Changes in 1.0.8 (27 Jan 1998)
- fixed offsets in contrib/asm386/gvmat32.asm (Gilles Vollant)
```

```
- fix gzgetc and gzputc for big endian systems (Markus Oberhumer)
- added compress2() to allow setting the compression level
- include sys/types.h to get off_t on some systems (Marc Lehmann & QingLong)
- use constant arrays for the static trees in trees.c instead of computing
  them at run time (thanks to Ken Raeburn for this suggestion). To create
  trees.h, compile with GEN_TREES_H and run "make test".
- check return code of example in "make test" and display result
- pass minigzip command line options to file_compress
- simplifying code of inflateSync to avoid gcc 2.8 bug

- support CC="gcc -Wall" in configure -s (QingLong)
- avoid a flush caused by ftell in gzopen for write mode (Ken Raeburn)
- fix test for shared library support to avoid compiler warnings
- zlib.lib -> zlib.dll in msdos/zlib.rc (Gilles Vollant)
- check for TARGET_OS_MAC in addition to MACOS (Brad Pettit)
- do not use fdopen for Metrowerks on Mac (Brad Pettit))
- add checks for gzputc and gzputc in example.c
- avoid warnings in gzio.c and deflate.c (Andreas Kleinert)
- use const for the CRC table (Ken Raeburn)
- fixed "make uninstall" for shared libraries
- use Tracev instead of Trace in infblock.c
- in example.c use correct compressed length for test_sync
- suppress +vnocompatwarnings in configure for HPUX (not always supported)

Changes in 1.0.7 (20 Jan 1998)
- fix gzseek which was broken in write mode
- return error for gzseek to negative absolute position
- fix configure for Linux (Chun-Chung Chen)
- increase stack space for MSC (Tim Wegner)
- get_crc_table and inflateSyncPoint are EXPORTed (Gilles Vollant)
- define EXPORTVA for gzprintf (Gilles Vollant)
- added man page zlib.3 (Rick Rodgers)
- for contrib/untgz, fix makedir() and improve Makefile

- check gzseek in write mode in example.c
- allocate extra buffer for seeks only if gzseek is actually called
- avoid signed/unsigned comparisons (Tim Wegner, Gilles Vollant)
- add inflateSyncPoint in zconf.h
- fix list of exported functions in nt/zlib.dnt and mdsos/zlib.def

Changes in 1.0.6 (19 Jan 1998)
- add functions gzprintf, gzputc, gzgetc, gztell, gzeof, gzseek, gzrewind and
  gzsetparams (thanks to Roland Giersig and Kevin Ruland for some of this code)
- Fix a deflate bug occurring only with compression level 0 (thanks to
  Andy Buckler for finding this one).
- In minigzip, pass transparently also the first byte for .Z files.
- return Z_BUF_ERROR instead of Z_OK if output buffer full in uncompress()
- check Z_FINISH in inflate (thanks to Marc Schluper)
- Implement deflateCopy (thanks to Adam Costello)
- make static libraries by default in configure, add --shared option.
- move MSDOS or Windows specific files to directory msdos
- suppress the notion of partial flush to simplify the interface
  (but the symbol Z_PARTIAL_FLUSH is kept for compatibility with 1.0.4)
- suppress history buffer provided by application to simplify the interface
  (this feature was not implemented anyway in 1.0.4)
- next_in and avail_in must be initialized before calling inflateInit or
  inflateInit2
- add EXPORT in all exported functions (for Windows DLL)
- added Makefile.nt (thanks to Stephen Williams)
- added the unsupported "contrib" directory:
   contrib/asm386/ by Gilles Vollant <info@winimage.com>
        386 asm code replacing longest_match().
   contrib/iostream/ by Kevin Ruland <kevin@rodin.wustl.edu>
        A C++ I/O streams interface to the zlib gz* functions
   contrib/iostream2/  by Tyge L^,vset <Tyge.Lovset@cmr.no>
        Another C++ I/O streams interface
```

```
   contrib/untgz/  by "Pedro A. Aranda Guti\irrez" <paag@tid.es>
        A very simple tar.gz file extractor using zlib
   contrib/visual-basic.txt by Carlos Rios <c_rios@sonda.cl>
        How to use compress(), uncompress() and the gz* functions from VB.
- pass params -f (filtered data), -h (huffman only), -1 to -9 (compression
  level) in minigzip (thanks to Tom Lane)

- use const for rommable constants in deflate
- added test for gzseek and gztell in example.c
- add undocumented function inflateSyncPoint() (hack for Paul Mackerras)
- add undocumented function zError to convert error code to string
  (for Tim Smithers)
- Allow compilation of gzio with -DNO_DEFLATE to avoid the compression code.
- Use default memcpy for Symantec MSDOS compiler.
- Add EXPORT keyword for check_func (needed for Windows DLL)
- add current directory to LD_LIBRARY_PATH for "make test"
- create also a link for libz.so.1
- added support for FUJITSU UXP/DS (thanks to Toshiaki Nomura)
- use $(SHAREDLIB) instead of libz.so in Makefile.in (for HPUX)
- added -soname for Linux in configure (Chun-Chung Chen,
- assign numbers to the exported functions in zlib.def (for Windows DLL)
- add advice in zlib.h for best usage of deflateSetDictionary
- work around compiler bug on Atari (cast Z_NULL in call of s->checkfn)
- allow compilation with ANSI keywords only enabled for TurboC in large model
- avoid "versionString"[0] (Borland bug)
- add NEED_DUMMY_RETURN for Borland
- use variable z_verbose for tracing in debug mode (L. Peter Deutsch).
- allow compilation with CC
- defined STDC for OS/2 (David Charlap)
- limit external names to 8 chars for MVS (Thomas Lund)
- in minigzip.c, use static buffers only for 16-bit systems
- fix suffix check for "minigzip -d foo.gz"
- do not return an error for the 2nd of two consecutive gzflush() (Felix Lee)
- use _fdopen instead of fdopen for MSC >= 6.0 (Thomas Fanslau)
- added makelcc.bat for lcc-win32 (Tom St Denis)
- in Makefile.dj2, use copy and del instead of install and rm (Frank Donahoe)
- Avoid expanded $Id$. Use "rcs -kb" or "cvs admin -kb" to avoid Id expansion.
- check for unistd.h in configure (for off_t)
- remove useless check parameter in inflate_blocks_free
- avoid useless assignment of s->check to itself in inflate_blocks_new
- do not flush twice in gzclose (thanks to Ken Raeburn)
- rename FOPEN as F_OPEN to avoid clash with /usr/include/sys/file.h
- use NO_ERRNO_H instead of enumeration of operating systems with errno.h
- work around buggy fclose on pipes for HP/UX
- support zlib DLL with BORLAND C++ 5.0 (thanks to Glenn Randers-Pehrson)
- fix configure if CC is already equal to gcc

Changes in 1.0.5 (3 Jan 98)
- Fix inflate to terminate gracefully when fed corrupted or invalid data
- Use const for rommable constants in inflate
- Eliminate memory leaks on error conditions in inflate
- Removed some vestigial code in inflate
- Update web address in README

Changes in 1.0.4 (24 Jul 96)
- In very rare conditions, deflate(s, Z_FINISH) could fail to produce an EOF
  bit, so the decompressor could decompress all the correct data but went
  on to attempt decompressing extra garbage data. This affected minigzip too.
- zlibVersion and gzerror return const char* (needed for DLL)
- port to RISCOS (no fdopen, no multiple dots, no unlink, no fileno)
- use z_error only for DEBUG (avoid problem with DLLs)

Changes in 1.0.3 (2 Jul 96)
- use z_streamp instead of z_stream *, which is now a far pointer in MSDOS
  small and medium models; this makes the library incompatible with previous
  versions for these models. (No effect in large model or on other systems.)
```

```
- return OK instead of BUF_ERROR if previous deflate call returned with
  avail_out as zero but there is nothing to do
- added memcmp for non STDC compilers
- define NO_DUMMY_DECL for more Mac compilers (.h files merged incorrectly)
- define __32BIT__ if __386__ or i386 is defined (pb. with Watcom and SCO)
- better check for 16-bit mode MSC (avoids problem with Symantec)

Changes in 1.0.2 (23 May 96)
- added Windows DLL support
- added a function zlibVersion (for the DLL support)
- fixed declarations using Bytef in infutil.c (pb with MSDOS medium model)
- Bytef is define's instead of typedef'd only for Borland C
- avoid reading uninitialized memory in example.c
- mention in README that the zlib format is now RFC1950
- updated Makefile.dj2
- added algorithm.doc

Changes in 1.0.1 (20 May 96) [1.0 skipped to avoid confusion]
- fix array overlay in deflate.c which sometimes caused bad compressed data
- fix inflate bug with empty stored block
- fix MSDOS medium model which was broken in 0.99
- fix deflateParams() which could generated bad compressed data.
- Bytef is define'd instead of typedef'ed (work around Borland bug)
- added an INDEX file
- new makefiles for DJGPP (Makefile.dj2), 32-bit Borland (Makefile.b32),
  Watcom (Makefile.wat), Amiga SAS/C (Makefile.sas)
- speed up adler32 for modern machines without auto-increment
- added -ansi for IRIX in configure
- static_init_done in trees.c is an int
- define unlink as delete for VMS
- fix configure for QNX
- add configure branch for SCO and HPUX
- avoid many warnings (unused variables, dead assignments, etc...)
- no fdopen for BeOS
- fix the Watcom fix for 32 bit mode (define FAR as empty)
- removed redefinition of Byte for MKWERKS
- work around an MWKERKS bug (incorrect merge of all .h files)

Changes in 0.99 (27 Jan 96)
- allow preset dictionary shared between compressor and decompressor
- allow compression level 0 (no compression)
- add deflateParams in zlib.h: allow dynamic change of compression level
  and compression strategy.
- test large buffers and deflateParams in example.c
- add optional "configure" to build zlib as a shared library
- suppress Makefile.qnx, use configure instead
- fixed deflate for 64-bit systems (detected on Cray)
- fixed inflate_blocks for 64-bit systems (detected on Alpha)
- declare Z_DEFLATED in zlib.h (possible parameter for deflateInit2)
- always return Z_BUF_ERROR when deflate() has nothing to do
- deflateInit and inflateInit are now macros to allow version checking
- prefix all global functions and types with z_ with -DZ_PREFIX
- make falloc completely reentrant (inftrees.c)
- fixed very unlikely race condition in ct_static_init
- free in reverse order of allocation to help memory manager
- use zlib-1.0/* instead of zlib/* inside the tar.gz
- make zlib warning-free with "gcc -O3 -Wall -Wwrite-strings -Wpointer-arith
  -Wconversion -Wstrict-prototypes -Wmissing-prototypes"
- allow gzread on concatenated .gz files
- deflateEnd now returns Z_DATA_ERROR if it was premature
- deflate is finally (?) fully deterministic (no matches beyond end of input)
- Document Z_SYNC_FLUSH
- add uninstall in Makefile
- Check for __cpluplus in zlib.h
- Better test in ct_align for partial flush
- avoid harmless warnings for Borland C++
```

```
- initialize hash_head in deflate.c
- avoid warning on fdopen (gzio.c) for HP cc -Aa
- include stdlib.h for STDC compilers
- include errno.h for Cray
- ignore error if ranlib doesn't exist
- call ranlib twice for NeXTSTEP
- use exec_prefix instead of prefix for libz.a
- renamed ct_* as _tr_* to avoid conflict with applications
- clear z->msg in inflateInit2 before any error return
- initialize opaque in example.c, gzio.c, deflate.c and inflate.c
- fixed typo in zconf.h (_GNUC__ => __GNUC__)
- check for WIN32 in zconf.h and zutil.c (avoid farmalloc in 32-bit mode)
- fix typo in Make_vms.com (f$trnlnm -> f$getsyi)
- in fcalloc, normalize pointer if size > 65520 bytes
- don't use special fcalloc for 32 bit Borland C++
- use STDC instead of __GO32__ to avoid redeclaring exit, calloc, etc...
- use Z_BINARY instead of BINARY
- document that gzclose after gzdopen will close the file
- allow "a" as mode in gzopen.
- fix error checking in gzread
- allow skipping .gz extra-field on pipes
- added reference to Perl interface in README
- put the crc table in FAR data (I dislike more and more the medium model :)
- added get_crc_table
- added a dimension to all arrays (Borland C can't count).
- workaround Borland C bug in declaration of inflate_codes_new & inflate_fast
- guard against multiple inclusion of *.h (for precompiled header on Mac)
- Watcom C pretends to be Microsoft C small model even in 32 bit mode.
- don't use unsized arrays to avoid silly warnings by Visual C++:
     warning C4746: 'inflate_mask' : unsized array treated as  '__far'
     (what's wrong with far data in far model?).
- define enum out of inflate_blocks_state to allow compilation with C++

Changes in 0.95 (16 Aug 95)
- fix MSDOS small and medium model (now easier to adapt to any compiler)
- inlined send_bits
- fix the final (:-) bug for deflate with flush (output was correct but
  not completely flushed in rare occasions).
- default window size is same for compression and decompression
  (it's now sufficient to set MAX_WBITS in zconf.h).
- voidp -> voidpf and voidnp -> voidp (for consistency with other
  typedefs and because voidnp was not near in large model).

Changes in 0.94 (13 Aug 95)
- support MSDOS medium model
- fix deflate with flush (could sometimes generate bad output)
- fix deflateReset (zlib header was incorrectly suppressed)
- added support for VMS
- allow a compression level in gzopen()
- gzflush now calls fflush
- For deflate with flush, flush even if no more input is provided.
- rename libgz.a as libz.a
- avoid complex expression in infcodes.c triggering Turbo C bug
- work around a problem with gcc on Alpha (in INSERT_STRING)
- don't use inline functions (problem with some gcc versions)
- allow renaming of Byte, uInt, etc... with #define.
- avoid warning about (unused) pointer before start of array in deflate.c
- avoid various warnings in gzio.c, example.c, infblock.c, adler32.c, zutil.c
- avoid reserved word 'new' in trees.c

Changes in 0.93 (25 June 95)
- temporarily disable inline functions
- make deflate deterministic
- give enough lookahead for PARTIAL_FLUSH
- Set binary mode for stdin/stdout in minigzip.c for OS/2
- don't even use signed char in inflate (not portable enough)
```

```
- fix inflate memory leak for segmented architectures

Changes in 0.92 (3 May 95)
- don't assume that char is signed (problem on SGI)
- Clear bit buffer when starting a stored block
- no memcpy on Pyramid
- suppressed inftest.c
- optimized fill_window, put longest_match inline for gcc
- optimized inflate on stored blocks.
- untabify all sources to simplify patches

Changes in 0.91 (2 May 95)
- Default MEM_LEVEL is 8 (not 9 for Unix) as documented in zlib.h
- Document the memory requirements in zconf.h
- added "make install"
- fix sync search logic in inflateSync
- deflate(Z_FULL_FLUSH) now works even if output buffer too short
- after inflateSync, don't scare people with just "lo world"
- added support for DJGPP

Changes in 0.9 (1 May 95)
- don't assume that zalloc clears the allocated memory (the TurboC bug
  was Mark's bug after all :)
- let again gzread copy uncompressed data unchanged (was working in 0.71)
- deflate(Z_FULL_FLUSH), inflateReset and inflateSync are now fully implemented
- added a test of inflateSync in example.c
- moved MAX_WBITS to zconf.h because users might want to change that.
- document explicitly that zalloc(64K) on MSDOS must return a normalized
  pointer (zero offset)
- added Makefiles for Microsoft C, Turbo C, Borland C++
- faster crc32()

Changes in 0.8 (29 April 95)
- added fast inflate (inffast.c)
- deflate(Z_FINISH) now returns Z_STREAM_END when done. Warning: this
  is incompatible with previous versions of zlib which returned Z_OK.
- work around a TurboC compiler bug (bad code for b << 0, see infutil.h)
  (actually that was not a compiler bug, see 0.81 above)
- gzread no longer reads one extra byte in certain cases
- In gzio destroy(), don't reference a freed structure
- avoid many warnings for MSDOS
- avoid the ERROR symbol which is used by MS Windows

Changes in 0.71 (14 April 95)
- Fixed more MSDOS compilation problems :( There is still a bug with
  TurboC large model.

Changes in 0.7 (14 April 95)
- Added full inflate support.
- Simplified the crc32() interface. The pre- and post-conditioning
  (one's complement) is now done inside crc32(). WARNING: this is
  incompatible with previous versions; see zlib.h for the new usage.

Changes in 0.61 (12 April 95)
- workaround for a bug in TurboC. example and minigzip now work on MSDOS.

Changes in 0.6 (11 April 95)
- added minigzip.c
- added gzdopen to reopen a file descriptor as gzFile
- added transparent reading of non-gziped files in gzread.
- fixed bug in gzread (don't read crc as data)
- fixed bug in destroy (gzio.c) (don't return Z_STREAM_END for gzclose).
- don't allocate big arrays in the stack (for MSDOS)
- fix some MSDOS compilation problems

Changes in 0.5:
```

```
1447 - do real compression in deflate.c. Z_PARTIAL_FLUSH is supported but
1448   not yet Z_FULL_FLUSH.
1449 - support decompression but only in a single step (forced Z_FINISH)
1450 - added opaque object for zalloc and zfree.
1451 - added deflateReset and inflateReset
1452 - added a variable zlib_version for consistency checking.
1453 - renamed the 'filter' parameter of deflateInit2 as 'strategy'.
1454   Added Z_FILTERED and Z_HUFFMAN_ONLY constants.

1456 Changes in 0.4:
1457 - avoid "zip" everywhere, use zlib instead of ziplib.
1458 - suppress Z_BLOCK_FLUSH, interpret Z_PARTIAL_FLUSH as block flush
1459   if compression method == 8.
1460 - added adler32 and crc32
1461 - renamed deflateOptions as deflateInit2, call one or the other but not both
1462 - added the method parameter for deflateInit2.
1463 - added inflateInit2
1464 - simplied considerably deflateInit and inflateInit by not supporting
1465   user-provided history buffer. This is supported only in deflateInit2
1466   and inflateInit2.

1468 Changes in 0.3:
1469 - prefix all macro names with Z_
1470 - use Z_FINISH instead of deflateEnd to finish compression.
1471 - added Z_HUFFMAN_ONLY
1472 - added gzerror()
```

```

5470 libz should be part of illumos
1002 Integrate zlib
**********************************************************
```

```
                Frequently Asked Questions about zlib

If your question is not there, please check the zlib home page
http://zlib.net/ which may have more recent information.
The lastest zlib FAQ is at http://zlib.net/zlib_faq.html

 1. Is zlib Y2K-compliant?

    Yes. zlib doesn't handle dates.

 2. Where can I get a Windows DLL version?

    The zlib sources can be compiled without change to produce a DLL.  See the
    file win32/DLL_FAQ.txt in the zlib distribution.  Pointers to the
    precompiled DLL are found in the zlib web site at http://zlib.net/ .

 3. Where can I get a Visual Basic interface to zlib?

    See
        * http://marknelson.us/1997/01/01/zlib-engine/
        * win32/DLL_FAQ.txt in the zlib distribution

 4. compress() returns Z_BUF_ERROR.

    Make sure that before the call of compress(), the length of the compressed
    buffer is equal to the available size of the compressed buffer and not
    zero.  For Visual Basic, check that this parameter is passed by reference
    ("as any"), not by value ("as long").

 5. deflate() or inflate() returns Z_BUF_ERROR.

    Before making the call, make sure that avail_in and avail_out are not zero.
    When setting the parameter flush equal to Z_FINISH, also make sure that
    avail_out is big enough to allow processing all pending input.  Note that a
    Z_BUF_ERROR is not fatal--another call to deflate() or inflate() can be
    made with more input or output space.  A Z_BUF_ERROR may in fact be
    unavoidable depending on how the functions are used, since it is not
    possible to tell whether or not there is more output pending when
    strm.avail_out returns with zero.  See http://zlib.net/zlib_how.html for a
    heavily annotated example.

 6. Where's the zlib documentation (man pages, etc.)?

    It's in zlib.h .  Examples of zlib usage are in the files test/example.c
    and test/minigzip.c, with more in examples/ .

 7. Why don't you use GNU autoconf or libtool or ...?

    Because we would like to keep zlib as a very small and simple package.
    zlib is rather portable and doesn't need much configuration.

 8. I found a bug in zlib.

    Most of the time, such problems are due to an incorrect usage of zlib.
    Please try to reproduce the problem with a small program and send the
    corresponding source to us at zlib@gzip.org .  Do not send multi-megabyte
    data files without prior agreement.
```

```
 9. Why do I get "undefined reference to gzputc"?

    If "make test" produces something like

       example.o(.text+0x154): undefined reference to `gzputc'

    check that you don't have old files libz.* in /usr/lib, /usr/local/lib or
    /usr/X11R6/lib. Remove any old versions, then do "make install".

10. I need a Delphi interface to zlib.

    See the contrib/delphi directory in the zlib distribution.

11. Can zlib handle .zip archives?

    Not by itself, no.  See the directory contrib/minizip in the zlib
    distribution.

12. Can zlib handle .Z files?

    No, sorry.  You have to spawn an uncompress or gunzip subprocess, or adapt
    the code of uncompress on your own.

13. How can I make a Unix shared library?

    By default a shared (and a static) library is built for Unix.  So:

    make distclean
    ./configure
    make

14. How do I install a shared zlib library on Unix?

    After the above, then:

    make install

    However, many flavors of Unix come with a shared zlib already installed.
    Before going to the trouble of compiling a shared version of zlib and
    trying to install it, you may want to check if it's already there!  If you
    can #include <zlib.h>, it's there.  The -lz option will probably link to
    it.  You can check the version at the top of zlib.h or with the
    ZLIB_VERSION symbol defined in zlib.h .

15. I have a question about OttoPDF.

    We are not the authors of OttoPDF. The real author is on the OttoPDF web
    site: Joel Hainley, jhainley@myndkryme.com.

16. Can zlib decode Flate data in an Adobe PDF file?

    Yes. See http://www.pdflib.com/ . To modify PDF forms, see
    http://sourceforge.net/projects/acroformtool/ .

17. Why am I getting this "register_frame_info not found" error on Solaris?

    After installing zlib 1.1.4 on Solaris 2.6, running applications using zlib
    generates an error such as:

        ld.so.1: rpm: fatal: relocation error: file /usr/local/lib/libz.so:
        symbol __register_frame_info: referenced symbol not found

    The symbol __register_frame_info is not part of zlib, it is generated by
    the C compiler (cc or gcc).  You must recompile applications using zlib
    which have this problem.  This problem is specific to Solaris.  See
```

http://www.sunfreeware.com for Solaris versions of zlib and applications using zlib.

18. Why does gzip give an error on a file I make with compress/deflate?

The compress and deflate functions produce data in the zlib format, which is different and incompatible with the gzip format. The gz* functions in zlib on the other hand use the gzip format. Both the zlib and gzip formats use the same compressed data format internally, but have different headers and trailers around the compressed data.

19. Ok, so why are there two different formats?

The gzip format was designed to retain the directory information about a single file, such as the name and last modification date. The zlib format on the other hand was designed for in-memory and communication channel applications, and has a much more compact header and trailer and uses a faster integrity check than gzip.

20. Well that's nice, but how do I make a gzip file in memory?

You can request that deflate write the gzip format instead of the zlib format using deflateInit2(). You can also request that inflate decode the gzip format using inflateInit2(). Read zlib.h for more details.

21. Is zlib thread-safe?

Yes. However any library routines that zlib uses and any application-provided memory allocation routines must also be thread-safe. zlib's gz* functions use stdio library routines, and most of zlib's functions use the library memory allocation routines by default. zlib's *Init* functions allow for the application to provide custom memory allocation routines.

Of course, you should only operate on any given zlib or gzip stream from a single thread at a time.

22. Can I use zlib in my commercial application?

Yes. Please read the license in zlib.h.

23. Is zlib under the GNU license?

No. Please read the license in zlib.h.

24. The license says that altered source versions must be "plainly marked". So what exactly do I need to do to meet that requirement?

You need to change the ZLIB_VERSION and ZLIB_VERNUM #defines in zlib.h. In particular, the final version number needs to be changed to "f", and an identification string should be appended to ZLIB_VERSION. Version numbers x.x.x.f are reserved for modifications to zlib by others than the zlib maintainers. For example, if the version of the base zlib you are altering is "1.2.3.4", then in zlib.h you should change ZLIB_VERNUM to 0x123f, and ZLIB_VERSION to something like "1.2.3.f-zachary-mods-v3". You can also update the version strings in deflate.c and inftrees.c.

For altered source distributions, you should also note the origin and nature of the changes in zlib.h, as well as in ChangeLog and README, along with the dates of the alterations. The origin should include at least your name (or your company's name), and an email address to contact for help or issues with the library.

Note that distributing a compiled zlib library along with zlib.h and zconf.h is also a source distribution, and so you should change ZLIB_VERSION and ZLIB_VERNUM and note the origin and nature of the changes in zlib.h as you would for a full source distribution.

25. Will zlib work on a big-endian or little-endian architecture, and can I exchange compressed data between them?

Yes and yes.

26. Will zlib work on a 64-bit machine?

Yes. It has been tested on 64-bit machines, and has no dependence on any data types being limited to 32-bits in length. If you have any difficulties, please provide a complete problem report to zlib@gzip.org

27. Will zlib decompress data from the PKWare Data Compression Library?

No. The PKWare DCL uses a completely different compressed data format than does PKZIP and zlib. However, you can look in zlib's contrib/blast directory for a possible solution to your problem.

28. Can I access data randomly in a compressed stream?

No, not without some preparation. If when compressing you periodically use Z_FULL_FLUSH, carefully write all the pending data at those points, and keep an index of those locations, then you can start decompression at those points. You have to be careful to not use Z_FULL_FLUSH too often, since it can significantly degrade compression. Alternatively, you can scan a deflate stream once to generate an index, and then use that index for random access. See examples/zran.c .

29. Does zlib work on MVS, OS/390, CICS, etc.?

It has in the past, but we have not heard of any recent evidence. There were working ports of zlib 1.1.4 to MVS, but those links no longer work. If you know of recent, successful applications of zlib on these operating systems, please let us know. Thanks.

30. Is there some simpler, easier to read version of inflate I can look at to understand the deflate format?

First off, you should read RFC 1951. Second, yes. Look in zlib's contrib/puff directory.

31. Does zlib infringe on any patents?

As far as we know, no. In fact, that was originally the whole point behind zlib. Look here for some more information:

http://www.gzip.org/#faq11

32. Can zlib work with greater than 4 GB of data?

Yes. inflate() and deflate() will process any amount of data correctly. Each call of inflate() or deflate() is limited to input and output chunks of the maximum value that can be stored in the compiler's "unsigned int" type, but there is no limit to the number of chunks. Note however that the strm.total_in and strm_total_out counters may be limited to 4 GB. These counters are provided as a convenience and are not used internally by inflate() or deflate(). The application can easily set up its own counters updated after each call of inflate() or deflate() to count beyond 4 GB. compress() and uncompress() may be limited to 4 GB, since they operate in a single call. gzseek() and gztell() may be limited to 4 GB depending on how zlib is compiled. See the zlibCompileFlags() function in zlib.h.

The word "may" appears several times above since there is a 4 GB limit only if the compiler's "long" type is 32 bits. If the compiler's "long" type is 64 bits, then the limit is 16 exabytes.

33. Does zlib have any security vulnerabilities?

    The only one that we are aware of is potentially in gzprintf(). If zlib is compiled to use sprintf() or vsprintf(), then there is no protection against a buffer overflow of an 8K string space (or other value as set by gzbuffer()), other than the caller of gzprintf() assuring that the output will not exceed 8K. On the other hand, if zlib is compiled to use snprintf() or vsnprintf(), which should normally be the case, then there is no vulnerability. The ./configure script will display warnings if an insecure variation of sprintf() will be used by gzprintf(). Also the zlibCompileFlags() function will return information on what variant of sprintf() is used by gzprintf().

    If you don't have snprintf() or vsnprintf() and would like one, you can find a portable implementation here:

        http://www.ijs.si/software/snprintf/

    Note that you should be using the most recent version of zlib. Versions 1.1.3 and before were subject to a double-free vulnerability, and versions 1.2.1 and 1.2.2 were subject to an access exception when decompressing invalid compressed data.

34. Is there a Java version of zlib?

    Probably what you want is to use zlib in Java. zlib is already included as part of the Java SDK in the java.util.zip package. If you really want a version of zlib written in the Java language, look on the zlib home page for links: http://zlib.net/ .

35. I get this or that compiler or source-code scanner warning when I crank it up to maximally-pedantic. Can't you guys write proper code?

    Many years ago, we gave up attempting to avoid warnings on every compiler in the universe. It just got to be a waste of time, and some compilers were downright silly as well as contradicted each other. So now, we simply make sure that the code always works.

36. Valgrind (or some similar memory access checker) says that deflate is performing a conditional jump that depends on an uninitialized value. Isn't that a bug?

    No. That is intentional for performance reasons, and the output of deflate is not affected. This only started showing up recently since zlib 1.2.x uses malloc() by default for allocations, whereas earlier versions used calloc(), which zeros out the allocated memory. Even though the code was correct, versions 1.2.4 and later was changed to not stimulate these checkers.

37. Will zlib read the (insert any ancient or arcane format here) compressed data format?

    Probably not. Look in the comp.compression FAQ for pointers to various formats and associated software.

38. How can I encrypt/decrypt zip files with zlib?

    zlib doesn't support encryption. The original PKZIP encryption is very weak and can be broken with freely available programs. To get strong encryption, use GnuPG, http://www.gnupg.org/ , which already includes zlib compression. For PKZIP compatible "encryption", look at http://www.info-zip.org/

39. What's the difference between the "gzip" and "deflate" HTTP 1.1 encodings?

    "gzip" is the gzip format, and "deflate" is the zlib format. They should

    probably have called the second one "zlib" instead to avoid confusion with the raw deflate compressed data format. While the HTTP 1.1 RFC 2616 correctly points to the zlib specification in RFC 1950 for the "deflate" transfer encoding, there have been reports of servers and browsers that incorrectly produce or expect raw deflate data per the deflate specification in RFC 1951, most notably Microsoft. So even though the "deflate" transfer encoding using the zlib format would be the more efficient approach (and in fact exactly what the zlib format was designed for), using the "gzip" transfer encoding is probably more reliable due to an unfortunate choice of name on the part of the HTTP 1.1 authors.

    Bottom line: use the gzip format for HTTP 1.1 encoding.

40. Does zlib support the new "Deflate64" format introduced by PKWare?

    No. PKWare has apparently decided to keep that format proprietary, since they have not documented it as they have previous compression formats. In any case, the compression improvements are so modest compared to other more modern approaches, that it's not worth the effort to implement.

41. I'm having a problem with the zip functions in zlib, can you help?

    There are no zip functions in zlib. You are probably using minizip by Giles Vollant, which is found in the contrib directory of zlib. It is not part of zlib. In fact none of the stuff in contrib is part of zlib. The files in there are not supported by the zlib authors. You need to contact the authors of the respective contribution for help.

42. The match.asm code in contrib is under the GNU General Public License. Since it's part of zlib, doesn't that mean that all of zlib falls under the GNU GPL?

    No. The files in contrib are not part of zlib. They were contributed by other authors and are provided as a convenience to the user within the zlib distribution. Each item in contrib has its own license.

43. Is zlib subject to export controls? What is its ECCN?

    zlib is not subject to export controls, and so is classified as EAR99.

44. Can you please sign these lengthy legal documents and fax them back to us so that we can use your software in our product?

    No. Go away. Shoo.

```
ZLIB DATA COMPRESSION LIBRARY

zlib 1.2.8 is a general purpose data compression library.  All the code is
thread safe.  The data format used by the zlib library is described by RFCs
(Request for Comments) 1950 to 1952 in the files
http://tools.ietf.org/html/rfc1950 (zlib format), rfc1951 (deflate format) and
rfc1952 (gzip format).

All functions of the compression library are documented in the file zlib.h
(volunteer to write man pages welcome, contact zlib@gzip.org).  A usage example
of the library is given in the file test/example.c which also tests that
the library is working correctly.  Another example is given in the file
test/minigzip.c.  The compression library itself is composed of all source
files in the root directory.

To compile all files and run the test program, follow the instructions given at
the top of Makefile.in.  In short "./configure; make test", and if that goes
well, "make install" should work for most flavors of Unix.  For Windows, use
one of the special makefiles in win32/ or contrib/vstudio/ .  For VMS, use
make_vms.com.

Questions about zlib should be sent to <zlib@gzip.org>, or to Gilles Vollant
<info@winimage.com> for the Windows DLL version.  The zlib home page is
http://zlib.net/ .  Before reporting a problem, please check this site to
verify that you have the latest version of zlib; otherwise get the latest
version and check whether the problem still exists or not.

PLEASE read the zlib FAQ http://zlib.net/zlib_faq.html before asking for help.

Mark Nelson <markn@ieee.org> wrote an article about zlib for the Jan.  1997
issue of Dr.  Dobb's Journal; a copy of the article is available at
http://marknelson.us/1997/01/01/zlib-engine/ .

The changes made in version 1.2.8 are documented in the file ChangeLog.

Unsupported third party contributions are provided in directory contrib/ .

zlib is available in Java using the java.util.zip package, documented at
http://java.sun.com/developer/technicalArticles/Programming/compression/ .

A Perl interface to zlib written by Paul Marquess <pmqs@cpan.org> is available
at CPAN (Comprehensive Perl Archive Network) sites, including
http://search.cpan.org/~pmqs/IO-Compress-Zlib/ .

A Python interface to zlib written by A.M. Kuchling <amk@amk.ca> is
available in Python 1.5 and later versions, see
http://docs.python.org/library/zlib.html .

zlib is built into tcl: http://wiki.tcl.tk/4610 .

An experimental package to read and write files in .zip format, written on top
of zlib by Gilles Vollant <info@winimage.com>, is available in the
contrib/minizip directory of zlib.

Notes for some targets:

- For Windows DLL versions, please see win32/DLL_FAQ.txt

- For 64-bit Irix, deflate.c must be compiled without any optimization. With
```

```
  -O, one libpng test fails. The test works in 32 bit mode (with the -n32
  compiler flag). The compiler bug has been reported to SGI.

- zlib doesn't work with gcc 2.6.3 on a DEC 3000/300LX under OSF/1 2.1 it works
  when compiled with cc.

- On Digital Unix 4.0D (formely OSF/1) on AlphaServer, the cc option -std1 is
  necessary to get gzprintf working correctly. This is done by configure.

- zlib doesn't work on HP-UX 9.05 with some versions of /bin/cc. It works with
  other compilers. Use "make test" to check your compiler.

- gzdopen is not supported on RISCOS or BEOS.

- For PalmOs, see http://palmzlib.sourceforge.net/

Acknowledgments:

  The deflate format used by zlib was defined by Phil Katz.  The deflate and
  zlib specifications were written by L.  Peter Deutsch.  Thanks to all the
  people who reported problems and suggested various improvements in zlib; they
  are too numerous to cite here.

```

```
         ZLIB version 1.2.8 for AS400 installation instructions

I) From an AS400 *SAVF file:

1)       Unpacking archive to an AS400 save file

On the AS400:

_        Create the ZLIB AS400 library:

         CRTLIB LIB(ZLIB) TYPE(*PROD) TEXT('ZLIB compression API library')

_        Create a work save file, for example:

                CRTSAVF FILE(ZLIB/ZLIBSAVF)

On a PC connected to the target AS400:

_        Unpack the save file image to a PC file "ZLIBSAVF"
_        Upload this file into the save file on the AS400, for example
                using ftp in BINARY mode.

2)       Populating the ZLIB AS400 source library

On the AS400:

_        Extract the saved objects into the ZLIB AS400 library using:

RSTOBJ OBJ(*ALL) SAVLIB(ZLIB) DEV(*SAVF) SAVF(ZLIB/ZLIBSAVF) RSTLIB(ZLIB)

3)       Customize installation:

_        Edit CL member ZLIB/TOOLS(COMPILE) and change parameters if needed,
                according to the comments.

_        Compile this member with:

         CRTCLPGM PGM(ZLIB/COMPILE) SRCFILE(ZLIB/TOOLS) SRCMBR(COMPILE)

4)       Compile and generate the service program:

_        This can now be done by executing:

         CALL PGM(ZLIB/COMPILE)

II) From the original source distribution:

1)       On the AS400, create the source library:

         CRTLIB LIB(ZLIB) TYPE(*PROD) TEXT('ZLIB compression API library')

2)       Create the source files:

         CRTSRCPF FILE(ZLIB/SOURCES) RCDLEN(112) TEXT('ZLIB library modules')
         CRTSRCPF FILE(ZLIB/H)       RCDLEN(112) TEXT('ZLIB library includes')
```

```
         CRTSRCPF FILE(ZLIB/TOOLS)   RCDLEN(112) TEXT('ZLIB library control utili

3)       From the machine hosting the distribution files, upload them (with
                FTP in text mode, for example) according to the following table:

     Original    AS400   AS400    AS400 AS400
     file        file    member   type  description
                 SOURCES                Original ZLIB C subprogram sources

     as400/readme.txt    README   TXT   Installation instructions

4)       Continue as in I)3).

Notes:  For AS400 ILE RPG programmers, a /copy member defining the ZLIB
                API prototypes for ILE RPG can be found in ZLIB/H(ZLIB.INC).
                Please read comments in this member for more information.

         Remember that most foreign textual data are ASCII coded: this
                implementation does not handle conversion from/to ASCII, so
                text data code conversions must be done explicitely.

         Mainly for the reason above, always open zipped files in binary mode.

#!/bin/sh
# configure script for zlib.
#
# Normally configure builds both a static and a shared library.
# If you want to build just a static library, use: ./configure --static
#
# To impose specific compiler or flags or install directory, use for example:
#    prefix=$HOME CC=cc CFLAGS="-O4" ./configure
# or for csh/tcsh users:
#    (setenv prefix $HOME; setenv CC cc; setenv CFLAGS "-O4"; ./configure)

# Incorrect settings of CC or CFLAGS may prevent creating a shared library.
# If you have problems, try without defining CC and CFLAGS before reporting
# an error.

ada/        by Dmitriy Anisimkov <anisimkov@yahoo.com>
        Support for Ada
        See http://zlib-ada.sourceforge.net/

amd64/      by Mikhail Teterin <mi@ALDAN.algebra.com>
        asm code for AMD64
        See patch at http://www.freebsd.org/cgi/query-pr.cgi?pr=bin/96393

asm686/     by Brian Raiter <breadbox@muppetlabs.com>
        asm code for Pentium and PPro/PII, using the AT&T (GNU as) syntax
        See http://www.muppetlabs.com/~breadbox/software/assembly.html

blast/      by Mark Adler <madler@alumni.caltech.edu>
        Decompressor for output of PKWare Data Compression Library (DCL)

delphi/     by Cosmin Truta <cosmint@cs.ubbcluj.ro>
        Support for Delphi and C++ Builder

dotzlib/    by Henrik Ravn <henrik@ravn.com>
        Support for Microsoft .Net and Visual C++ .Net

gcc_gvmat64/by Gilles Vollant <info@winimage.com>
        GCC Version of x86 64-bit (AMD64 and Intel EM64t) code for x64
        assembler to replace longest_match() and inflate_fast()

infback9/   by Mark Adler <madler@alumni.caltech.edu>
        Unsupported diffs to infback to decode the deflate64 format

inflate86/  by Chris Anderson <christop@charm.net>
        Tuned x86 gcc asm code to replace inflate_fast()

iostream/   by Kevin Ruland <kevin@rodin.wustl.edu>
        A C++ I/O streams interface to the zlib gz* functions

iostream2/  by Tyge Lˆ,vset <Tyge.Lovset@cmr.no>
        Another C++ I/O streams interface

iostream3/  by Ludwig Schwardt <schwardt@sun.ac.za>

  11 --  This demo program provided by Dr Steve Sangwine <sjs@essex.ac.uk>
  12 --
  13 --  Demonstration of a problem with Zlib-Ada (already fixed) when a buffer
  14 --  of exactly the correct size is used for decompressed data, and the last
  15 --  few bytes passed in to Zlib are checksum bytes.

  17 --  This program compresses a string of text, and then decompresses the
  18 --  compressed text into a buffer of the same size as the original text.

  20 with Ada.Streams; use Ada.Streams;
  21 with Ada.Text_IO;

  23 with ZLib; use ZLib;

  25 procedure Buffer_Demo is
  26    EOL  : Character renames ASCII.LF;
  27    Text : constant String
  28      := "Four score and seven years ago our fathers brought forth," & EOL &
  29         "upon this continent, a new nation, conceived in liberty," & EOL &
  30         "and dedicated to the proposition that 'all men are created equal'.";

  32    Source : Stream_Element_Array (1 .. Text'Length);
  33    for Source'Address use Text'Address;

  35 begin
  36    Ada.Text_IO.Put (Text);
  37    Ada.Text_IO.New_Line;
  38    Ada.Text_IO.Put_Line
  39      ("Uncompressed size : " & Positive'Image (Text'Length) & " bytes");

  41    declare
  42       Compressed_Data : Stream_Element_Array (1 .. Text'Length);
  43       L               : Stream_Element_Offset;
  44    begin
  45       Compress : declare
  46          Compressor : Filter_Type;

                        ZLib for Ada thick binding (ZLib.Ada)
                        Release 1.3

ZLib.Ada is a thick binding interface to the popular ZLib data
compression library, available at http://www.gzip.org/zlib/.
It provides Ada-style access to the ZLib C library.

        Here are the main changes since ZLib.Ada 1.2:

- Attension: ZLib.Read generic routine have a initialization requirement
  for Read_Last parameter now. It is a bit incompartible with previous version,
  but extends functionality, we could use new parameters Allow_Read_Some and
  Flush now.

- Added Is_Open routines to ZLib and ZLib.Streams packages.

- Add pragma Assert to check Stream_Element is 8 bit.

- Fix extraction to buffer with exact known decompressed size. Error reported by
  Steve Sangwine.

- Fix definition of ULong (changed to unsigned_long), fix regression on 64 bits
  computers. Patch provided by Pascal Obry.

- Add Status_Error exception definition.

- Add pragma Assertion that Ada.Streams.Stream_Element size is 8 bit.

        How to build ZLib.Ada under GNAT

You should have the ZLib library already build on your computer, before
building ZLib.Ada. Make the directory of ZLib.Ada sources current and
issue the command:

  gnatmake test -largs -L<directory where libz.a is> -lz

Or use the GNAT project file build for GNAT 3.15 or later:

  gnatmake -Pzlib.gpr -L<directory where libz.a is>

        How to build ZLib.Ada under Aonix ObjectAda for Win32 7.2.2

1. Make a project with all *.ads and *.adb files from the distribution.
2. Build the libz.a library from the ZLib C sources.
3. Rename libz.a to z.lib.
4. Add the library z.lib to the project.
5. Add the libc.lib library from the ObjectAda distribution to the project.
6. Build the executable using test.adb as a main procedure.

        How to use ZLib.Ada

The source files test.adb and read.adb are small demo programs that show
the main functionality of ZLib.Ada.

The routines from the package specifications are commented.

   No_Flush      : constant Flush_Mode;
   --  Regular way for compression, no flush

   Partial_Flush : constant Flush_Mode;
   --  Will be removed, use Z_SYNC_FLUSH instead

   Sync_Flush    : constant Flush_Mode;
   --  All pending output is flushed to the output buffer and the output
   --  is aligned on a byte boundary, so that the decompressor can get all
   --  input data available so far. (In particular avail_in is zero after the
   --  call if enough output space has been provided  before the call.)
   --  Flushing may degrade compression for some compression algorithms and so
   --  it should be used only when necessary.

   Block_Flush   : constant Flush_Mode;
   --  Z_BLOCK requests that inflate() stop
   --  if and when it get to the next deflate block boundary. When decoding the
   --  zlib or gzip format, this will cause inflate() to return immediately
   --  after the header and before the first block. When doing a raw inflate,
   --  inflate() will go ahead and process the first block, and will return
   --  when it gets to the end of that block, or when it runs out of data.

   Full_Flush    : constant Flush_Mode;
   --  All output is flushed as with SYNC_FLUSH, and the compression state
   --  is reset so that decompression can restart from this point if previous
   --  compressed data has been damaged or if random access is desired. Using
   --  Full_Flush too often can seriously degrade the compression.

   Finish        : constant Flush_Mode;
   --  Just for tell the compressor that input data is complete.

   ----------------------------------
   -- Compression strategy constants --

5470 libz should be part of illumos
1002 Integrate zlib
**********************************************************
```

This is a patched version of zlib, modified to use
Pentium-Pro-optimized assembly code in the deflation algorithm. The
files changed/added by this patch are:

README.686
match.S

The speedup that this patch provides varies, depending on whether the
compiler used to build the original version of zlib falls afoul of the
PPro's speed traps. My own tests show a speedup of around 10-20% at
the default compression level, and 20-30% using -9, against a version
compiled using gcc 2.7.2.3. Your mileage may vary.

Note that this code has been tailored for the PPro/PII in particular,
and will not perform particuarly well on a Pentium.

If you are using an assembler other than GNU as, you will have to
translate match.S to use your assembler's syntax. (Have fun.)

Brian Raiter
breadbox@muppetlabs.com
April, 1998

Added for zlib 1.1.3:

The patches come from
http://www.muppetlabs.com/~breadbox/software/assembly.html

To compile zlib with this asm file, copy match.S to the zlib directory
then do:

```
CFLAGS="-O3 -DASMV" ./configure
make OBJA=match.o
```

Update:

I've been ignoring these assembly routines for years, believing that
gcc's generated code had caught up with it sometime around gcc 2.95
and the major rearchitecting of the Pentium 4. However, I recently
learned that, despite what I believed, this code still has some life
in it. On the Pentium 4 and AMD64 chips, it continues to run about 8%
faster than the code produced by gcc 4.1.

In acknowledgement of its continuing usefulness, I've altered the
license to match that of the rest of zlib. Share and Enjoy!

/* blast.c
 * Copyright (C) 2003, 2012 Mark Adler
 * For conditions of distribution and use, see copyright notice in blast.h
 * version 1.2, 24 Oct 2012
 *
 * blast.c decompresses data compressed by the PKWare Compression Library.
 * This function provides functionality similar to the explode() function of
 * the PKWare library, hence the name "blast".
 *
 * This decompressor is based on the excellent format description provided by
 * Ben Rudiak-Gould in comp.compression on August 13, 2001.  Interestingly, the
 * example Ben provided in the post is incorrect.  The distance 110001 should
 * instead be 111000.  When corrected, the example byte stream becomes:
 *
 *    00 04 82 24 25 8f 80 7f
 *
 * which decompresses to "AIAIAIAIAIAIA" (without the quotes).
 */

/*
 * Change history:
 *
 * 1.0  12 Feb 2003     - First version
 * 1.1  16 Feb 2003     - Fixed distance check for > 4 GB uncompressed data
 * 1.2  24 Oct 2012     - Add note about using binary mode in stdio
 *                      - Fix comparisons of differently signed integers
 */

 * Decode a code from the stream s using huffman table h.  Return the symbol or
 * a negative value if there is an error.  If all of the lengths are zero, i.e.
 * an empty code, or if the code is incomplete and an invalid code is received,
 * then -9 is returned after reading MAXBITS bits.
 *
 * Format notes:
 *
 * - The codes as stored in the compressed data are bit-reversed relative to
 *   a simple integer ordering of codes of the same lengths.  Hence below the
 *   bits are pulled from the compressed data one at a time and used to
 *   build the code value reversed from what is in the stream in order to
 *   permit simple integer comparisons for decoding.
 *
 * - The first code for the shortest length is all ones.  Subsequent codes of
 *   the same length are simply integer decrements of the previous code.  When
 *   moving up a length, a one bit is appended to the code.  For a complete
 *   code, the last code of the longest length will be all zeros.  To support
 *   this ordering, the bits pulled during decoding are inverted to apply the
 *   more "natural" ordering starting with all zeros and incrementing.

/*
 * Decode PKWare Compression Library stream.
 *
 * Format notes:
 *
 * - First byte is 0 if literals are uncoded or 1 if they are coded.  Second
 *   byte is 4, 5, or 6 for the number of extra bits in the distance code.
 *   This is the base-2 logarithm of the dictionary size minus six.
 *
 * - Compressed data is a combination of literals and length/distance pairs
 *   terminated by an end code.  Literals are either Huffman coded or
 *   uncoded bytes.  A length/distance pair is a coded length followed by a
 *   coded distance to represent a string that occurs earlier in the
 *   uncompressed data that occurs again at the current location.
 *
 * - A bit preceding a literal or length/distance pair indicates which comes
 *   next, 0 for literals, 1 for length/distance.
 *
 * - If literals are uncoded, then the next eight bits are the literal, in the
```

```
 *   normal bit order in th stream, i.e. no bit-reversal is needed. Similarly,
 *   no bit reversal is needed for either the length extra bits or the distance
 *   extra bits.
 *
 * - Literal bytes are simply written to the output.  A length/distance pair is
 *   an instruction to copy previously uncompressed bytes to the output.  The
 *   copy is from distance bytes back in the output stream, copying for length
 *   bytes.
 *
 * - Distances pointing before the beginning of the output data are not
 *   permitted.
 *
 * - Overlapped copies, where the length is greater than the distance, are
 *   allowed and common.  For example, a distance of one and a length of 518
 *   simply copies the last byte 518 times.  A distance of four and a length of
 *   twelve copies the last four bytes three times.  A simple forward copy
 *   ignoring whether the length is greater than the distance or not implements
 *   this correctly.

/* Definitions for input/output functions passed to blast().  See below for
 * what the provided functions need to do.
 */

int blast(blast_in infun, void *inhow, blast_out outfun, void *outhow);
/* Decompress input to output using the provided infun() and outfun() calls.
 * On success, the return value of blast() is zero.  If there is an error in
 * the source data, i.e. it is not in the proper format, then a negative value
 * is returned.  If there is not enough input available or there is not enough
 * output space, then a positive error is returned.
 *
 * The input function is invoked: len = infun(how, &buf), where buf is set by
 * infun() to point to the input buffer, and infun() returns the number of
 * available bytes there.  If infun() returns zero, then blast() returns with
 * an input error.  (blast() only asks for input if it needs it.)  inhow is for
 * use by the application to pass an input descriptor to infun(), if desired.
 *
 * The output function is invoked: err = outfun(how, buf, len), where the bytes
 * to be written are buf[0..len-1].  If err is not zero, then blast() returns
 * with an output error.  outfun() is always called with len <= 4096.  outhow
```

```
 * is for use by the application to pass an output descriptor to outfun(), if
 * desired.
 *
 * The return codes are:
 *
 *   2:  ran out of input before completing decompression
 *   1:  output error before completing decompression
 *   0:  successful decompression
 *  -1:  literal flag not zero or one
 *  -2:  dictionary size not in 4..6
 *  -3:  distance is too far back
 *
 * At the bottom of blast.c is an example program that uses blast() that can be
 * compiled to produce a command-line decompression filter by defining TEST.

    property OnProgress: TNotifyEvent read FOnProgress write FOnProgress;
    constructor Create(Strm: TStream);
  end;

{ TCompressionStream compresses data on the fly as data is written to it, and
  stores the compressed data to another stream.
```

```
  TCompressionStream is write-only and strictly sequential. Reading from the
  stream will raise an exception. Using Seek to move the stream pointer
  will raise an exception.

  Output data is cached internally, written to the output stream only when
  the internal output buffer is full.  All pending output data is flushed
  when the stream is destroyed.

  The Position property returns the number of uncompressed bytes of
  data that have been written to the stream so far.

  CompressionRate returns the on-the-fly percentage by which the original
  data has been compressed:  (1 - (CompressedBytes / UncompressedBytes)) * 100
  If raw data size = 100 and compressed data size = 25, the CompressionRate
  is 75%

  The OnProgress event is called each time the output buffer is filled and
  written to the output stream.  This is useful for updating a progress
  indicator when you are writing a large chunk of data to the compression
  stream in a single call.}

  TCompressionLevel = (clNone, clFastest, clDefault, clMax);

  TCompressionStream = class(TCustomZlibStream)
  private
    function GetCompressionRate: Single;
  public
    constructor Create(CompressionLevel: TCompressionLevel; Dest: TStream);
    destructor Destroy; override;
    function Read(var Buffer; Count: Longint): Longint; override;
    function Write(const Buffer; Count: Longint): Longint; override;
    function Seek(Offset: Longint; Origin: Word): Longint; override;
    property CompressionRate: Single read GetCompressionRate;
    property OnProgress;
  end;

{ TDecompressionStream decompresses data on the fly as data is read from it.

  Compressed data comes from a separate source stream.  TDecompressionStream
  is read-only and unidirectional; you can seek forward in the stream, but not
  backwards.  The special case of setting the stream position to zero is
  allowed.  Seeking forward decompresses data until the requested position in
  the uncompressed data has been reached.  Seeking backwards, seeking relative
  to the end of the stream, requesting the size of the stream, and writing to
  the stream will raise an exception.

  The Position property returns the number of bytes of uncompressed data that
  have been read from the stream so far.

  The OnProgress event is called each time the internal input buffer of
  compressed data is exhausted and the next block is read from the input stream.
  This is useful for updating a progress indicator when you are reading a
  large chunk of data from the decompression stream in a single call.}

Overview
========

This directory contains an update to the ZLib interface unit,
distributed by Borland as a Delphi supplemental component.

The original ZLib unit is Copyright (c) 1997,99 Borland Corp.,
and is based on zlib version 1.0.4.  There are a series of bugs
and security problems associated with that old zlib version, and
we recommend the users to update their ZLib unit.

Summary of modifications
========================

- Improved makefile, adapted to zlib version 1.2.1.

- Some field types from TZStreamRec are changed from Integer to
  Longint, for consistency with the zlib.h header, and for 64-bit
  readiness.

- The zlib_version constant is updated.

- The new Z_RLE strategy has its corresponding symbolic constant.

- The allocation and deallocation functions and function types
  (TAlloc, TFree, zlibAllocMem and zlibFreeMem) are now cdecl,
  and _malloc and _free are added as C RTL stubs.  As a result,
  the original C sources of zlib can be compiled out of the box,
  and linked to the ZLib unit.

Suggestions for improvements
============================

Currently, the ZLib unit provides only a limited wrapper around
the zlib library, and much of the original zlib functionality is
missing.  Handling compressed file formats like ZIP/GZIP or PNG
cannot be implemented without having this functionality.
Applications that handle these formats are either using their own,
duplicated code, or not using the ZLib unit at all.

Here are a few suggestions:

- Checksum class wrappers around adler32() and crc32(), similar
  to the Java classes that implement the java.util.zip.Checksum
  interface.

- The ability to read and write raw deflate streams, without the
  zlib stream header and trailer.  Raw deflate streams are used
  in the ZIP file format.

- The ability to read and write gzip streams, used in the GZIP
  file format, and normally produced by the gzip program.

- The ability to select a different compression strategy, useful
  to PNG and MNG image compression, and to multimedia compression
  in general.  Besides the compression level
```

```
    TCompressionLevel = (clNone, clFastest, clDefault, clMax);

  which, in fact, could have used the 'z' prefix and avoided
  TColor-like symbols

    TCompressionLevel = (zcNone, zcFastest, zcDefault, zcMax);

  there could be a compression strategy

    TCompressionStrategy = (zsDefault, zsFiltered, zsHuffmanOnly, zsRle);

- ZIP and GZIP stream handling via TStreams.

[assembly: AssemblyProduct("")]
[assembly: AssemblyCopyright("(c) 2004 by Henrik Ravn")]
[assembly: AssemblyTrademark("")]
[assembly: AssemblyCulture("")]

//
// Version information for an assembly consists of the following four values:
//
//      Major Version
//      Minor Version
//      Build Number
//      Revision
//
// You can specify all the values or you can default the Revision and Build Numb
// by using the '*' as shown below:

[assembly: AssemblyVersion("1.0.*")]

//
// In order to sign your assembly you must specify a key to use. Refer to the
// Microsoft .NET Framework documentation for more information on assembly signi
//
// Use the attributes below to control which key is used for signing.
//
// Notes:
//   (*) If no key is specified, the assembly is not signed.
//   (*) KeyName refers to a key that has been installed in the Crypto Service
//       Provider (CSP) on your machine. KeyFile refers to a file which contains
//       a key.
//   (*) If the KeyFile and the KeyName values are both specified, the
//       following processing occurs:
//       (1) If the KeyName can be found in the CSP, that key is used.
//       (2) If the KeyName does not exist and the KeyFile does exist, the key
//           in the KeyFile is installed into the CSP and used.
//   (*) In order to create a KeyFile, you can use the sn.exe (Strong Name) util
//       When specifying the KeyFile, the location of the KeyFile should be
//       relative to the project output directory which is
//       %Project Directory%\obj\<configuration>. For example, if your KeyFile i
//       located in the project directory, you would specify the AssemblyKeyFile
//       attribute as [assembly: AssemblyKeyFile("..\\..\\mykey.snk")]
//   (*) Delay Signing is an advanced option - see the Microsoft .NET Framework
//       documentation for more information on this.
//

```

```
This directory contains a .Net wrapper class library for the ZLib1.dll

The wrapper includes support for inflating/deflating memory buffers,
.Net streaming wrappers for the gz streams part of zlib, and wrappers
for the checksum parts of zlib. See DotZLib/UnitTests.cs for examples.

Directory structure:
--------------------

LICENSE_1_0.txt       - License file.
readme.txt            - This file.
DotZLib.chm           - Class library documentation
DotZLib.build         - NAnt build file
DotZLib.sln           - Microsoft Visual Studio 2003 solution file

DotZLib\*.cs          - Source files for the class library

Unit tests:
-----------
The file DotZLib/UnitTests.cs contains unit tests for use with NUnit 2.1 or high
To include unit tests in the build, define nunit before building.

Build instructions:
-------------------

1. Using Visual Studio.Net 2003:
   Open DotZLib.sln in VS.Net and build from there. Output file (DotZLib.dll)
   will be found ./DotZLib/bin/release or ./DotZLib/bin/debug, depending on
   you are building the release or debug version of the library. Check
   DotZLib/UnitTests.cs for instructions on how to include unit tests in the
   build.

2. Using NAnt:
   Open a command prompt with access to the build environment and run nant
   in the same directory as the DotZLib.build file.
   You can define 2 properties on the nant command-line to control the build:
   debug={true|false} to toggle between release/debug builds (default=true).
   nunit={true|false} to include or esclude unit tests (default=true).
   Also the target clean will remove binaries.
   Output file (DotZLib.dll) will be found in either ./DotZLib/bin/release
   or ./DotZLib/bin/debug, depending on whether you are building the release
   or debug version of the library.

   Examples:
     nant -D:debug=false -D:nunit=false
       will build a release mode version of the library without unit tests.
     nant
       will build a debug version of the library with unit tests
     nant clean
       will remove all previously built files.

190 /*
191    strm provides the memory allocation functions and window buffer on input,
192    and provides information on the unused input on return.  For Z_DATA_ERROR
```

```
193    returns, strm will also provide an error message.

195    in() and out() are the call-back input and output functions.  When
196    inflateBack() needs more input, it calls in().  When inflateBack() has
197    filled the window with output, or when it completes with data in the
198    window, it calls out() to write out the data.  The application must not
199    change the provided input until in() is called again or inflateBack()
200    returns.  The application must not change the window/output buffer until
201    inflateBack() returns.

203    in() and out() are called with a descriptor parameter provided in the
204    inflateBack() call.  This parameter can be a structure that provides the
205    information required to do the read or write, as well as accumulated
206    information on the input and output such as totals and check values.

208    in() should return zero on failure.  out() should return non-zero on
209    failure.  If either in() or out() fails, than inflateBack() returns a
210    Z_BUF_ERROR.  strm->next_in can be checked for Z_NULL to see whether it
211    was in() or out() that caused in the error.  Otherwise,  inflateBack()
212    returns Z_STREAM_END on success, Z_DATA_ERROR for an deflate format
213    error, or Z_MEM_ERROR if it could not allocate memory for the state.
214    inflateBack() can also return Z_STREAM_ERROR if the input parameters
215    are not correct, i.e. strm is Z_NULL or the state was not initialized.

/* infback9.h -- header for using inflateBack9 functions
 * Copyright (C) 2003 Mark Adler
 * For conditions of distribution and use, see copyright notice in zlib.h
 */

/*
 * This header file and associated patches provide a decoder for PKWare's
 * undocumented deflate64 compression method (method 9).  Use with infback9.c,
 * inftree9.h, inftree9.c, and inffix9.h.  These patches are not supported.
 * This should be compiled with zlib, since it uses zutil.h and zutil.o.
 * This code has not yet been tested on 16-bit architectures.  See the
 * comments in zlib.h for inflateBack() usage.  These functions are used
 * identically, except that there is no windowBits parameter, and a 64K
 * window must be provided.  Also if int's are 16 bits, then a zero for
 * the third parameter of the "out" function actually means 65536UL.
 * zlib.h must be included before this header file.

    /*
       Process a set of code lengths to create a canonical Huffman code.  The
       code lengths are lens[0..codes-1].  Each length corresponds to the
       symbols 0..codes-1.  The Huffman code is generated by first sorting the
       symbols by length from short to long, and retaining the symbol order
       for codes with equal lengths.  Then the code starts with all zero bits
       for the first code of the shortest length, and the codes are integer
       increments for the same length, and zeros are appended as the length
       increases.  For the deflate format, these bits are stored backwards
       from their more natural integer increment ordering, and so when the
       decoding tables are built in the large loop below, the integer codes
       are incremented backwards.

       This routine assumes, but does not check, that all of the entries in
       lens[] are in the range 0..MAXBITS.  The caller must assure this.
       1..MAXBITS is interpreted as that code length.  zero means that that
       symbol does not occur in this code.

       The codes are sorted by computing a count of codes for each length,
       creating from that a table of starting indices for each length in the
       sorted table, and then entering the symbols in order in the sorted
       table.  The sorted table is work[], with that space being provided by
       the caller.

       The length counts are used for other purposes as well, i.e. finding
       the minimum and maximum length codes, determining if there are any
       codes at all, checking for a valid set of lengths, and looking ahead
       at length counts to determine sub-table sizes when building the
       decoding tables.
     */

    /* accumulate lengths for codes (assumes lens[] all in 0..MAXBITS) */
    for (len = 0; len <= MAXBITS; len++)
        count[len] = 0;
    for (sym = 0; sym < codes; sym++)
        count[lens[sym]]++;

    /* bound code lengths, force root to be within code lengths */
    root = *bits;
    for (max = MAXBITS; max >= 1; max--)
        if (count[max] != 0) break;
    if (root > max) root = max;
    if (max == 0) return -1;            /* no codes! */
    for (min = 1; min <= MAXBITS; min++)
        if (count[min] != 0) break;
    if (root < min) root = min;

    /* check for an over-subscribed or incomplete set of lengths */
    left = 1;
    for (len = 1; len <= MAXBITS; len++) {
```

```
        left <<= 1;
        left -= count[len];
        if (left < 0) return -1;        /* over-subscribed */
    }
    if (left > 0 && (type == CODES || max != 1))
        return -1;                      /* incomplete set */

    /* generate offsets into symbol table for each length for sorting */
    offs[1] = 0;
    for (len = 1; len < MAXBITS; len++)
        offs[len + 1] = offs[len] + count[len];

    /* sort symbols by length, by symbol order within each length */
    for (sym = 0; sym < codes; sym++)
        if (lens[sym] != 0) work[offs[lens[sym]]++] = (unsigned short)sym;

    /*
       Create and fill in decoding tables.  In this loop, the table being
       filled is at next and has curr index bits.  The code being used is huff
       with length len.  That code is converted to an index by dropping drop
       bits off of the bottom.  For codes where len is less than drop + curr,
       those top drop + curr - len bits are incremented through all values to
       fill the table with replicated entries.

       root is the number of index bits for the root table.  When len exceeds
       root, sub-tables are created pointed to by the root entry with an index
       of the low root bits of huff.  This is saved in low to check for when a
       new sub-table should be started.  drop is zero when the root table is
       being filled, and drop is root when sub-tables are being filled.

       When a new sub-table is needed, it is necessary to look ahead in the
       code lengths to determine what size sub-table is needed.  The length
       counts are used for this, and so count[] is decremented as codes are
       entered in the tables.

       used keeps track of how many table entries have been allocated from the
       provided *table space.  It is checked for LENS and DIST tables against
       the constants ENOUGH_LENS and ENOUGH_DISTS to guard against changes in
       the initial root table size constants.  See the comments in inftree9.h
       for more information.

       sym increments through all symbols, and the loop terminates when
       all codes of length max, i.e. all codes, have been processed.  This
       routine permits incomplete codes, so another loop after this one fills
       in the rest of the decoding tables with invalid code markers.

/* Structure for decoding tables.  Each entry provides either the
   information needed to do the operation requested by the code that
   indexed that table entry, or it provides a pointer to another
   table that indexes more bits of the code.  op indicates whether
   the entry is a pointer to another table, a literal, a length or
   distance, an end-of-block, or an invalid code.  For a table
   pointer, the low four bits of op is the number of index bits of
   that table.  For a length or distance, the low four bits of op
   is the number of extra bits to get after the code.  bits is
   the number of bits in this code or part of the code to drop off
   of the bit buffer.  val is the actual byte to output in the case
   of a literal, the base length or distance, or the offset from
   the current table to the next table.  Each entry is four bytes. */

/* inffas86.c is a hand tuned assembler version of
 *
 * inffast.c -- fast decoding
 * Copyright (C) 1995-2003 Mark Adler
 * For conditions of distribution and use, see copyright notice in zlib.h
 *
 * Copyright (C) 2003 Chris Anderson <christop@charm.net>
 * Please use the copyright conditions above.
 *
 * Dec-29-2003 -- I added AMD64 inflate asm support.  This version is also
 * slightly quicker on x86 systems because, instead of using rep movsb to copy
 * data, it uses rep movsw, which moves data in 2-byte chunks instead of single
 * bytes.  I've tested the AMD64 code on a Fedora Core 1 + the x86_64 updates
 * from http://fedora.linux.duke.edu/fc1_x86_64
 * which is running on an Athlon 64 3000+ / Gigabyte GA-K8VT800M system with
 * 1GB ram.  The 64-bit version is about 4% faster than the 32-bit version,
 * when decompressing mozilla-source-1.3.tar.gz.
 *
 * Mar-13-2003 -- Most of this is derived from inffast.S which is derived from
 * the gcc -S output of zlib-1.2.0/inffast.c.  Zlib-1.2.0 is in beta release at
 * the moment.  I have successfully compiled and tested this code with gcc2.96,
 * gcc3.2, icc5.0, msvc6.0.  It is very close to the speed of inffast.S
 * compiled with gcc -DNO_MMX, but inffast.S is still faster on the P3 with MMX
 * enabled.  I will attempt to merge the MMX code into this version.  Newer
 * versions of this and inffast.S can be found at
 * http://www.eetbeetee.com/zlib/ and http://www.charm.net/~christop/zlib/

/* Mark Adler's comments from inffast.c: */

/*
   Decode literal, length, and distance codes and write out the resulting
   literal and match bytes until either not enough input or output is
   available, an end-of-block is encountered, or a data error is encountered.
   When large enough input and output buffers are supplied to inflate(), for
   example, a 16K input buffer and a 64K output buffer, more than 95% of the
   inflate execution time is spent in this routine.

   Entry assumptions:

        state->mode == LEN
        strm->avail_in >= 6
        strm->avail_out >= 258
        start >= strm->avail_out
        state->bits < 8

   On return, state->mode is one of:

        LEN -- ran out of enough output space or enough available input
        TYPE -- reached end of block code, inflate() to interpret next block
        BAD -- error in block data

   Notes:

    - The maximum input bits used by a length/distance pair is 15 bits for the
      length code, 5 bits for the length extra, 15 bits for the distance code,
      and 13 bits for the distance extra.  This totals 48 bits, or six bytes.
      Therefore if strm->avail_in >= 6, then there is enough input to avoid
      checking for available input while decoding.

    - The maximum bytes that a single length/distance pair can output is 258
      bytes, which is the maximum length that can be coded.  inflate_fast()
      requires strm->avail_out >= 258 for each loop to avoid checking for
      output space.

/*
 * inffast.S is a hand tuned assembler version of:
 *
 * inffast.c -- fast decoding
 * Copyright (C) 1995-2003 Mark Adler
 * For conditions of distribution and use, see copyright notice in zlib.h
 *
 * Copyright (C) 2003 Chris Anderson <christop@charm.net>
 * Please use the copyright conditions above.
 *
 * This version (Jan-23-2003) of inflate_fast was coded and tested under
 * GNU/Linux on a pentium 3, using the gcc-3.2 compiler distribution.  On that
 * machine, I found that gzip style archives decompressed about 20% faster than
 * the gcc-3.2 -O3 -fomit-frame-pointer compiled version.  Your results will
 * depend on how large of a buffer is used for z_stream.next_in & next_out
 * (8K-32K worked best for my 256K cpu cache) and how much overhead there is in
 * stream processing I/O and crc32/addler32.  In my case, this routine used
 * 70% of the cpu time and crc32 used 20%.
 *
 * I am confident that this version will work in the general case, but I have
 * not tested a wide variety of datasets or a wide variety of platforms.
 *
 * Jan-24-2003 -- Added -DUSE_MMX define for slightly faster inflating.
 * It should be a runtime flag instead of compile time flag...
 *
 * Jan-26-2003 -- Added runtime check for MMX support with cpuid instruction.
 * With -DUSE_MMX, only MMX code is compiled.  With -DNO_MMX, only non-MMX code
 * is compiled.  Without either option, runtime detection is enabled.  Runtime
 * detection should work on all modern cpus and the recomended algorithm (flip
 * ID bit on eflags and then use the cpuid instruction) is used in many
 * multimedia applications.  Tested under win2k with gcc-2.95 and gas-2.12
 * distributed with cygwin3.  Compiling with gcc-2.95 -c inffast.S -o
 * inffast.obj generates a COFF object which can then be linked with MSVC++
 * compiled code.  Tested under FreeBSD 4.7 with gcc-2.95.
 *
 * Jan-28-2003 -- Tested Athlon XP... MMX mode is slower than no MMX (and
 * slower than compiler generated code).  Adjusted cpuid check to use the MMX
 * code only for Pentiums < P4 until I have more data on the P4.  Speed
 * improvment is only about 15% on the Athlon when compared with code generated
 * with MSVC++.  Not sure yet, but I think the P4 will also be slower using the
 * MMX mode because many of it's x86 ALU instructions execute in .5 cycles and
 * have less latency than MMX ops.  Added code to buffer the last 11 bytes of
 * the input stream since the MMX code grabs bits in chunks of 32, which
 * differs from the inffast.c algorithm.  I don't think there would have been
 * read overruns where a page boundary was crossed (a segfault), but there
 * could have been overruns when next_in ends on unaligned memory (unintialized
 * memory read).
 *
 * Mar-13-2003 -- P4 MMX is slightly slower than P4 NO_MMX.  I created a C
 * version of the non-MMX code so that it doesn't depend on zstrm and zstate
 * structure offsets which are hard coded in this file.  This was last tested
 * with zlib-1.2.0 which is currently in beta testing, newer versions of this
 * and inffas86.c can be found at http://www.eetbeetee.com/zlib/ and
 * http://www.charm.net/~christop/zlib/

**********************************************************
```

These classes provide a C++ stream interface to the zlib library. It allows you to do things like:

```
  gzofstream outf("blah.gz");
  outf << "These go into the gzip file " << 123 << endl;
```

It does this by deriving a specialized stream buffer for gzipped files, which is the way Stroustrup would have done it. :->

The gzifstream and gzofstream classes were originally written by Kevin Ruland and made available in the zlib contrib/iostream directory. The older version sti compiles under gcc 2.xx, but not under gcc 3.xx, which sparked the development o this version.

The new classes are as standard-compliant as possible, closely following the approach of the standard library's fstream classes. It compiles under gcc versio 3.2 and 3.3, but not under gcc 2.xx. This is mainly due to changes in the standa library naming scheme. The new version of gzifstream/gzofstream/gzfilebuf differ from the previous one in the following respects:

- added showmanyc
- added setbuf, with support for unbuffered output via setbuf(0,0)
- a few bug fixes of stream behavior
- gzipped output file opened with default compression level instead of maximum l
- setcompressionlevel()/strategy() members replaced by single setcompression()

     491 Wed Apr  1 15:57:10 2015
new/usr/src/lib/zlib/common/contrib/iostream3/TODO
5470 libz should be part of illumos
1002 Integrate zlib
**********************************************************
```

```
Possible upgrades to gzfilebuf:

- The ability to do putback (e.g. putbackfail)

- The ability to seek (zlib supports this, but could be slow/tricky)

- Simultaneous read/write access (does it make sense?)

- Support for ios_base::ate open mode

- Locale support?

- Check public interface to see which calls give problems
  (due to dependence on library internals)

- Override operator<<(ostream&, gzfilebuf*) to allow direct copying
  of stream buffer to stream ( i.e. os << is.rdbuf(); )
```

```

416
417 ;;; Test the strings for equality, 8 bytes at a time. At the end,
418 ;;; adjust rdx so that it is offset to the exact byte that mismatched.
419 ;;;
420 ;;; We already know at this point that the first three bytes of the
421 ;;; strings match each other, and they can be safely passed over before
422 ;;; starting the compare loop. So what this code does is skip over 0-3
423 ;;; bytes, as much as necessary in order to dword-align the edi
424 ;;; pointer. (rsi will still be misaligned three times out of four.)
425 ;;;
426 ;;; It should be confessed that this loop usually does not represent
427 ;;; much of the total running time. Replacing it with a more
428 ;;; straightforward "rep cmpsb" would not drastically degrade
429 ;;; performance.

/* inffas8664.c is a hand tuned assembler version of inffast.c - fast decoding
 * version for AMD64 on Windows using Microsoft C compiler
 *
 * Copyright (C) 1995-2003 Mark Adler
 * For conditions of distribution and use, see copyright notice in zlib.h
 *
 * Copyright (C) 2003 Chris Anderson <christop@charm.net>
 * Please use the copyright conditions above.
 *
 * 2005 - Adaptation to Microsoft C Compiler for AMD64 by Gilles Vollant
 *
 * inffas8664.c call function inffas8664fnc in inffasx64.asm
 *  inffasx64.asm is automatically convert from AMD64 portion of inffas86.c
 *
 * Dec-29-2003 -- I added AMD64 inflate asm support.  This version is also
 * slightly quicker on x86 systems because, instead of using rep movsb to copy
 * data, it uses rep movsw, which moves data in 2-byte chunks instead of single
 * bytes.  I've tested the AMD64 code on a Fedora Core 1 + the x86_64 updates
 * from http://fedora.linux.duke.edu/fc1_x86_64
 * which is running on an Athlon 64 3000+ / Gigabyte GA-K8VT800M system with
 * 1GB ram.  The 64-bit version is about 4% faster than the 32-bit version,
 * when decompressing mozilla-source-1.3.tar.gz.
 *
 * Mar-13-2003 -- Most of this is derived from inffast.S which is derived from
 * the gcc -S output of zlib-1.2.0/inffast.c.  Zlib-1.2.0 is in beta release at
 * the moment.  I have successfully compiled and tested this code with gcc2.96,
 * gcc3.2, icc5.0, msvc6.0.  It is very close to the speed of inffast.S
 * compiled with gcc -DNO_MMX, but inffast.S is still faster on the P3 with MMX
 * enabled.  I will attempt to merge the MMX code into this version.  Newer
 * versions of this and inffast.S can be found at
 * http://www.eetbeetee.com/zlib/ and http://www.charm.net/~christop/zlib/
 *

/* Mark Adler's comments from inffast.c: */

/*
   Decode literal, length, and distance codes and write out the resulting
   literal and match bytes until either not enough input or output is
   available, an end-of-block is encountered, or a data error is encountered.
   When large enough input and output buffers are supplied to inflate(), for
   example, a 16K input buffer and a 64K output buffer, more than 95% of the
   inflate execution time is spent in this routine.

   Entry assumptions:

        state->mode == LEN
        strm->avail_in >= 6
        strm->avail_out >= 258
        start >= strm->avail_out
        state->bits < 8

   On return, state->mode is one of:

```

```
        LEN -- ran out of enough output space or enough available input
        TYPE -- reached end of block code, inflate() to interpret next block
        BAD -- error in block data

   Notes:

    - The maximum input bits used by a length/distance pair is 15 bits for the
      length code, 5 bits for the length extra, 15 bits for the distance code,
      and 13 bits for the distance extra.  This totals 48 bits, or six bytes.
      Therefore if strm->avail_in >= 6, then there is enough input to avoid
      checking for available input while decoding.

    - The maximum bytes that a single length/distance pair can output is 258
      bytes, which is the maximum length that can be coded.  inflate_fast()
      requires strm->avail_out >= 258 for each loop to avoid checking for
      output space.
 */

```
; inffasx64.asm is a hand tuned assembler version of inffast.c - fast decoding
; version for AMD64 on Windows using Microsoft C compiler
;
; inffasx64.asm is automatically convert from AMD64 portion of inffas86.c
; inffasx64.asm is called by inffas8664.c, which contain more info.

; to compile this file, I use option
;   ml64.exe /Flinffasx64 /c /Zi inffasx64.asm
;   with Microsoft Macro Assembler (x64) for AMD64
;

; This file compile with Microsoft Macro Assembler (x64) for AMD64
;
;   ml64.exe is given with Visual Studio 2005/2008/2010 and Windows WDK
;
;   (you can get Windows WDK with ml64 for AMD64 from
;      http://www.microsoft.com/whdc/Devtools/wdk/default.mspx for low price)
;

Summary
-------
This directory contains ASM implementations of the functions
longest_match() and inflate_fast(), for 64 bits x86 (both AMD64 and Intel EM64t)
for use with Microsoft Macro Assembler (x64) for AMD64 and Microsoft C++ 64 bits

gvmat64.asm is written by Gilles Vollant (2005), by using Brian Raiter 686/32 bi
   assembly optimized version from Jean-loup Gailly original longest_match funct

inffasx64.asm and inffas8664.c were written by Chris Anderson, by optimizing
   original function from Mark Adler

Use instructions
----------------
Assemble the .asm files using MASM and put the object files into the zlib source
directory.  You can also get object files here:

     http://www.winimage.com/zLibDll/zlib124_masm_obj.zip

define ASMV and ASMINF in your project. Include inffas8664.c in your source tree
and inffasx64.obj and gvmat64.obj as object to link.

Build instructions
------------------
run bld_64.bat with Microsoft Macro Assembler (x64) for AMD64 (ml64.exe)

ml64.exe is given with Visual Studio 2005, Windows 2003 server DDK

You can get Windows 2003 server DDK with ml64 and cl for AMD64 from
  http://www.microsoft.com/whdc/devtools/ddk/default.mspx for low price)
```

;/* inffas32.asm is a hand tuned assembler version of inffast.c -- fast decoding
; *
; * inffas32.asm is derivated from inffas86.c, with translation of assembly code
; *
; * Copyright (C) 1995-2003 Mark Adler
; * For conditions of distribution and use, see copyright notice in zlib.h
; *
; * Copyright (C) 2003 Chris Anderson <christop@charm.net>
; * Please use the copyright conditions above.
; *
; * Mar-13-2003 -- Most of this is derived from inffast.S which is derived from
; * the gcc -S output of zlib-1.2.0/inffast.c.  Zlib-1.2.0 is in beta release at
; * the moment.  I have successfully compiled and tested this code with gcc2.96,
; * gcc3.2, icc5.0, msvc6.0.  It is very close to the speed of inffast.S
; * compiled with gcc -DNO_MMX, but inffast.S is still faster on the P3 with MMX
; * enabled.  I will attempt to merge the MMX code into this version.  Newer
; * versions of this and inffast.S can be found at
; * http://www.eetbeetee.com/zlib/ and http://www.charm.net/~christop/zlib/
; *
; * 2005 : modification by Gilles Vollant
; */
; For Visual C++ 4.x and higher and ML 6.x and higher
;   ml.exe is in directory \MASM611C of Win95 DDK
;   ml.exe is also distributed in http://www.masm32.com/masmdl.htm
;    and in VC++2003 toolkit at http://msdn.microsoft.com/visualc/vctoolkit2003/
;

307 ;;;         *(ushf*)match != scan_start) continue;
308 ;;;     [...]
309 ;;; } while ((cur_match = prev[cur_match & wmask]) > limit
310 ;;;          && --chain_length != 0);
311 ;;;
312 ;;; Here is the inner loop of the function. The function will spend the
313 ;;; majority of its time in this loop, and majority of that time will
314 ;;; be spent in the first ten instructions.
315 ;;;
316 ;;; Within this loop:
317 ;;; ebx = scanend
318 ;;; ecx = curmatch
319 ;;; edx = chainlenwmask - i.e., ((chainlen << 16) | wmask)
320 ;;; esi = windowbestlen - i.e., (window + bestlen)
321 ;;; edi = prev
322 ;;; ebp = limit
323
324 LookupLoop:
```

```
325         and ecx, edx
326         movzx   ecx, word ptr [edi + ecx*2]
327         cmp ecx, ebp
328         jbe LeaveNow
329         sub edx, 00010000h
330         js  LeaveNow
331 LoopEntry:  movzx   eax, word ptr [esi + ecx - 1]
332         cmp eax, ebx
333         jnz LookupLoop
334         mov eax, [window]
335         movzx   eax, word ptr [eax + ecx]
336         cmp eax, [scanstart]
337         jnz LookupLoop
338
339 ;;; Store the current value of chainlen.
340
341         mov [chainlenwmask], edx
342
343 ;;; Point edi to the string under scrutiny, and esi to the string we
344 ;;; are hoping to match it up with. In actuality, esi and edi are
345 ;;; both pointed (MAX_MATCH_8 - scanalign) bytes ahead, and edx is
346 ;;; initialized to -(MAX_MATCH_8 - scanalign).
347
348         mov esi, [window]
349         mov edi, [scan]
350         add esi, ecx
351         mov eax, [scanalign]
352         mov edx, 0fffffef8h; -(MAX_MATCH_8)
353         lea edi, [edi + eax + 0108h] ;MAX_MATCH_8]
354         lea esi, [esi + eax + 0108h] ;MAX_MATCH_8]
355
356 ;;; Test the strings for equality, 8 bytes at a time. At the end,
357 ;;; adjust edx so that it is offset to the exact byte that mismatched.
358 ;;;
359 ;;; We already know at this point that the first three bytes of the
360 ;;; strings match each other, and they can be safely passed over before
361 ;;; starting the compare loop. So what this code does is skip over 0-3
362 ;;; bytes, as much as necessary in order to dword-align the edi
363 ;;; pointer. (esi will still be misaligned three times out of four.)
364 ;;;
365 ;;; It should be confessed that this loop usually does not represent
366 ;;; much of the total running time. Replacing it with a more
367 ;;; straightforward "rep cmpsb" would not drastically degrade
368 ;;; performance.
369

Summary
-------
This directory contains ASM implementations of the functions
longest_match() and inflate_fast().

Use instructions
----------------
Assemble using MASM, and copy the object files into the zlib source
directory, then run the appropriate makefile, as suggested below.  You can
donwload MASM from here:

    http://www.microsoft.com/downloads/details.aspx?displaylang=en&FamilyID=7a1c

You can also get objects files here:

    http://www.winimage.com/zLibDll/zlib124_masm_obj.zip

Build instructions
------------------
* With Microsoft C and MASM:
nmake -f win32/Makefile.msc LOC="-DASMV -DASMINF" OBJA="match686.obj inffas32.ob

* With Borland C and TASM:
make -f win32/Makefile.bor LOCAL_ZLIB="-DASMV -DASMINF" OBJA="match686.obj inffa

```

MiniZip - Copyright (c) 1998-2010 - by Gilles Vollant - version 1.1 64 bits from

Introduction
---------------------
MiniZip 1.1 is built from MiniZip 1.0 by Gilles Vollant ( http://www.winimage.co

When adding ZIP64 support into minizip it would result into risk of breaking com
All possible work was done for compatibility.

Background
---------------------
When adding ZIP64 support Mathias Svensson found that Even Rouault have added ZI
support for unzip.c into minizip for a open source project called gdal ( http://

That was used as a starting point. And after that ZIP64 support was added to zip
some refactoring and code cleanup was also done.

Changed from MiniZip 1.0 to MiniZip 1.1
---------------------------------------
* Added ZIP64 support for unzip ( by Even Rouault )
* Added ZIP64 support for zip ( by Mathias Svensson )
* Reverted some changed that Even Rouault did.
* Bunch of patches received from Gulles Vollant that he received for MiniZip fro
* Added unzip patch for BZIP Compression method (patch create by Daniel Borca)
* Added BZIP Compress method for zip
* Did some refactoring and code cleanup

  1 /* crypt.h -- base code for crypt/uncrypt ZIPfile

  4    Version 1.01e, February 12th, 2005

  6    Copyright (C) 1998-2005 Gilles Vollant

  8    This code is a modified version of crypting code in Infozip distribution

 10    The encryption/decryption parts of this source code (as opposed to the
 11    non-echoing password parts) were originally written in Europe.  The
 12    whole source package can be freely distributed, including from the USA.
 13    (Prior to January 2000, re-export from the US was a violation of US law.)

 15    This encryption code is a direct transcription of the algorithm from
 16    Roger Schlafly, described by Phil Katz in the file appnote.txt.  This
 17    file (appnote.txt) is distributed with the PKZIP program (even in the
 18    version without encryption capabilities).

 20    If you don't need crypting in your application, just define symbols
 21    NOCRYPT and NOUNCRYPT.

 23    This code support the "Traditional PKWARE Encryption".

 25    The new AES encryption added on Zip format by Winzip (see the page
 26    http://www.winzip.com/aes_info.htm ) and PKWare PKZip 5.x Strong
 27    Encryption is not supported.

.SH NAME
miniunzip - uncompress and examine ZIP archives
.SH SYNOPSIS
.B miniunzip
.RI [ -exvlo ]
zipfile [ files_to_extract ] [-d tempdir]
.SH DESCRIPTION
.B minizip
is a simple tool which allows the extraction of compressed file
archives in the ZIP format used by the MS-DOS utility PKZIP.  It was
written as a demonstration of the
.IR zlib (3)
library and therefore lack many of the features of the
.IR unzip (1)
program.
.SH OPTIONS
A number of options are supported.  With the exception of
.BI \-d\  tempdir
these must be supplied before any
other arguments and are:
.TP
.BI \-l\ ,\ \-\-v
List the files in the archive without extracting them.
.TP
.B \-o
Overwrite files without prompting for confirmation.
.TP
.B \-x
Extract files (default).
.PP
The
.I zipfile
argument is the name of the archive to process. The next argument can be used
to specify a single file to extract from the archive.

Lastly, the following option can be specified at the end of the command-line:
.TP
.BI \-d\  tempdir
Extract the archive in the directory
.I tempdir
rather than the current directory.
.SH SEE ALSO
.BR minizip (1),
.BR zlib (3),
.BR unzip (1).
.SH AUTHOR
```

```
This program was written by Gilles Vollant.  This manual page was
written by Mark Brown <broonie@sirena.org.uk>. The -d tempdir option
was added by Dirk Eddelbuettel <edd@debian.org>.
```

.SH NAME
minizip - create ZIP archives
.SH SYNOPSIS
.B minizip
.RI [ -o ]
zipfile [ " files" ... ]
.SH DESCRIPTION
.B minizip
is a simple tool which allows the creation of compressed file archives
in the ZIP format used by the MS-DOS utility PKZIP.  It was written as
a demonstration of the
.IR zlib (3)
library and therefore lack many of the features of the
.IR zip (1)
program.
.SH OPTIONS
The first argument supplied is the name of the ZIP archive to create or
.RI -o
in which case it is ignored and the second argument treated as the
name of the ZIP file.  If the ZIP file already exists it will be
overwritten.
.PP
Subsequent arguments specify a list of files to place in the ZIP
archive.  If none are specified then an empty archive will be created.
.SH SEE ALSO
.BR miniunzip (1),
.BR zlib (3),
.BR zip (1).
.SH AUTHOR
This program was written by Gilles Vollant.  This manual page was
written by Mark Brown <broonie@sirena.org.uk>.

/* unzip.c -- IO for uncompress .zip files using zlib
   Version 1.1, February 14h, 2010
   part of the MiniZip project - ( http://www.winimage.com/zLibDll/minizip.html

         Copyright (C) 1998-2010 Gilles Vollant (minizip) ( http://www.winimage.

         Modifications of Unzip for Zip64
         Copyright (C) 2007-2008 Even Rouault

         Modifications for Zip64 support on both zip and unzip
         Copyright (C) 2009-2010 Mathias Svensson ( http://result42.com )

         For more info read MiniZip_info.txt

  ---------------------------------------------------------------------------
  Decryption code comes from crypt.c by Info-ZIP but has been greatly reduced in
  compatibility with older software. The following is from the original crypt.c.
  Code woven in by Terry Thorsen 1/2003.

  Copyright (c) 1990-2000 Info-ZIP.  All rights reserved.

  See the accompanying file LICENSE, version 2000-Apr-09 or later
  (the contents of which are also included in zip.h) for terms of use.
  If, for some reason, all these files are missing, the Info-ZIP license
  also may be found at:  ftp://ftp.info-zip.org/pub/infozip/license.html

        crypt.c (full version) by Info-ZIP.      Last revised:  [see crypt.h]

  The encryption/decryption parts of this source code (as opposed to the
  non-echoing password parts) were originally written in Europe.  The
  whole source package can be freely distributed, including from the USA.
  (Prior to January 2000, re-export from the US was a violation of US law.)

        This encryption code is a direct transcription of the algorithm from
  Roger Schlafly, described by Phil Katz in the file appnote.txt.  This
  file (appnote.txt) is distributed with the PKZIP program (even in the
  version without encryption capabilities).

        ---------------------------------------------------------------------

        Changes in unzip.c

        2007-2008 - Even Rouault - Addition of cpl_unzGetCurrentFileZStreamPos
  2007-2008 - Even Rouault - Decoration of symbol names unz* -> cpl_unz*
  2007-2008 - Even Rouault - Remove old C style function prototypes
  2007-2008 - Even Rouault - Add unzip support for ZIP64

        Copyright (C) 2007-2008 Even Rouault

        Oct-2009 - Mathias Svensson - Removed cpl_* from symbol names (Even Roua
  Oct-2009 - Mathias Svensson - Fixed problem if uncompressed size was > 4G and
                                should only read the compressed/uncompressed siz
                                the size from normal header was 0xFFFFFFFF

This directory contains a Pascal (Delphi, Kylix) interface to the
zlib data compression library.

Directory listing

zlibd32.mak	makefile for Borland C++
example.pas	usage example of zlib
zlibpas.pas	the Pascal interface to zlib
readme.txt	this file

Compatibility notes

- Although the name "zlib" would have been more normal for the
  zlibpas unit, this name is already taken by Borland's ZLib unit.
  This is somehow unfortunate, because that unit is not a genuine
  interface to the full-fledged zlib functionality, but a suite of
  class wrappers around zlib streams. Other essential features,
  such as checksums, are missing.
  It would have been more appropriate for that unit to have a name
  like "ZStreams", or something similar.

- The C and zlib-supplied types int, uInt, long, uLong, etc. are
  translated directly into Pascal types of similar sizes (Integer,
  LongInt, etc.), to avoid namespace pollution. In particular,
  there is no conversion of unsigned int into a Pascal unsigned
  integer. The Word type is non-portable and has the same size
  (16 bits) both in a 16-bit and in a 32-bit environment, unlike
  Integer. Even if there is a 32-bit Cardinal type, there is no
  real need for unsigned int in zlib under a 32-bit environment.

- Except for the callbacks, the zlib function interfaces are
  assuming the calling convention normally used in Pascal
  (__pascal for DOS and Windows16, __fastcall for Windows32).
  Since the cdecl keyword is used, the old Turbo Pascal does
  not work with this interface.

- The gz* function interfaces are not translated, to avoid
  interfacing problems with the C runtime library. Besides,
    gzprintf(gzFile file, const char *format, ...)
  cannot be translated into Pascal.

Legal issues

The zlibpas interface is:

```
Puff -- A Simple Inflate
3 Mar 2003
Mark Adler
madler@alumni.caltech.edu

What this is --

puff.c provides the routine puff() to decompress the deflate data format.  It
does so more slowly than zlib, but the code is about one-fifth the size of the
inflate code in zlib, and written to be very easy to read.

Why I wrote this --

puff.c was written to document the deflate format unambiguously, by virtue of
being working C code.  It is meant to supplement RFC 1951, which formally
describes the deflate format.  I have received many questions on details of the
deflate format, and I hope that reading this code will answer those questions.
puff.c is heavily commented with details of the deflate format, especially
those little nooks and cranies of the format that might not be obvious from a
specification.

puff.c may also be useful in applications where code size or memory usage is a
very limited resource, and speed is not as important.

How to use it --

Well, most likely you should just be reading puff.c and using zlib for actual
applications, but if you must ...

Include puff.h in your code, which provides this prototype:

int puff(unsigned char *dest,           /* pointer to destination pointer */
         unsigned long *destlen,        /* amount of output space */
         unsigned char *source,         /* pointer to source data pointer */
         unsigned long *sourcelen);     /* amount of input available */

Then you can call puff() to decompress a deflate stream that is in memory in
its entirety at source, to a sufficiently sized block of memory for the
decompressed data at dest.  puff() is the only external symbol in puff.c  The
only C library functions that puff.c needs are setjmp() and longjmp(), which
are used to simplify error checking in the code to improve readabilty.  puff.c
does no memory allocation, and uses less than 2K bytes off of the stack.

If destlen is not enough space for the uncompressed data, then inflate will
return an error without writing more than destlen bytes.  Note that this means
that in order to decompress the deflate data successfully, you need to know
the size of the uncompressed data ahead of time.

If needed, puff() can determine the size of the uncompressed data with no
output space.  This is done by passing dest equal to (unsigned char *)0.  Then
the initial value of *destlen is ignored and *destlen is set to the length of
the uncompressed data.  So if the size of the uncompressed data is not known,
then two passes of puff() can be used--first to determine the size, and second
to do the actual inflation after allocating the appropriate memory.  Not
pretty, but it works.  (This is one of the reasons you should be using zlib.)

The deflate format is self-terminating.  If the deflate stream does not end
in *sourcelen bytes, puff() will return an error without reading at or past
endsource.
```

```
On return, *sourcelen is updated to the amount of input data consumed, and
*destlen is updated to the size of the uncompressed data.  See the comments
in puff.c for the possible return codes for puff().
```

```

/*
 * puff.c
 * Copyright (C) 2002-2013 Mark Adler
 * For conditions of distribution and use, see copyright notice in puff.h
 * version 2.3, 21 Jan 2013
 *
 * puff.c is a simple inflate written to be an unambiguous way to specify the
 * deflate format.  It is not written for speed but rather simplicity.  As a
 * side benefit, this code might actually be useful when small code is more
 * important than speed, such as bootstrap applications.  For typical deflate
 * data, zlib's inflate() is about four times as fast as puff().  zlib's
 * inflate compiles to around 20K on my machine, whereas puff.c compiles to
 * around 4K on my machine (a PowerPC using GNU cc).  If the faster decode()
 * function here is used, then puff() is only twice as slow as zlib's
 * inflate().
 *
 * All dynamically allocated memory comes from the stack.  The stack required
 * is less than 2K bytes.  This code is compatible with 16-bit int's and
 * assumes that long's are at least 32 bits.  puff.c uses the short data type,
 * assumed to be 16 bits, for arrays in order to to conserve memory.  The code
 * works whether integers are stored big endian or little endian.
 *
 * In the comments below are "Format notes" that describe the inflate process
 * and document some of the less obvious aspects of the format.  This source
 * code is meant to supplement RFC 1951, which formally describes the deflate
 * format:
 *
 *    http://www.zlib.org/rfc-deflate.html
 */

/*
 * Change history:
 *
 * 1.0  10 Feb 2002     - First version
 * 1.1  17 Feb 2002     - Clarifications of some comments and notes
 *                      - Update puff() dest and source pointers on negative
 *                        errors to facilitate debugging deflators
 *                      - Remove longest from struct huffman -- not needed
 *                      - Simplify offs[] index in construct()
 *                      - Add input size and checking, using longjmp() to
 *                        maintain easy readability
 *                      - Use short data type for large arrays
 *                      - Use pointers instead of long to specify source and
 *                        destination sizes to avoid arbitrary 4 GB limits
 * 1.2  17 Mar 2002     - Add faster version of decode(), doubles speed (!),
 *                        but leave simple version for readabilty
 *                      - Make sure invalid distances detected if pointers
 *                        are 16 bits
 *                      - Fix fixed codes table error
 *                      - Provide a scanning mode for determining size of
 *                        uncompressed data
 * 1.3  20 Mar 2002     - Go back to lengths for puff() parameters [Gailly]
 *                      - Add a puff.h file for the interface
 *                      - Add braces in puff() for else do [Gailly]
 *                      - Use indexes instead of pointers for readability
 * 1.4  31 Mar 2002     - Simplify construct() code set check
 *                      - Fix some comments
 *                      - Add FIXLCODES #define
 * 1.5   6 Apr 2002     - Minor comment fixes
 * 1.6   7 Aug 2002     - Minor format changes
```

```
 * 1.7   3 Mar 2003     - Added test code for distribution
 *                      - Added zlib-like license
 * 1.8   9 Jan 2004     - Added some comments on no distance codes case
 * 1.9  21 Feb 2008     - Fix bug on 16-bit integer architectures [Pohland]
 *                      - Catch missing end-of-block symbol error
 * 2.0  25 Jul 2008     - Add #define to permit distance too far back
 *                      - Add option in TEST code for puff to write the data
 *                      - Add option in TEST code to skip input bytes
 *                      - Allow TEST code to read from piped stdin
 * 2.1   4 Apr 2010     - Avoid variable initialization for happier compilers
 *                      - Avoid unsigned comparisons for even happier compilers
 * 2.2  25 Apr 2010     - Fix bug in variable initializations [Oberhumer]
 *                      - Add const where appropriate [Oberhumer]
 *                      - Split if's and ?'s for coverage testing
 *                      - Break out test code to separate file
 *                      - Move NIL to puff.h
 *                      - Allow incomplete code only if single code length is 1
 *                      - Add full code coverage test to Makefile
 * 2.3  21 Jan 2013     - Check for invalid code length codes in dynamic blocks
 */

    short *count;       /* number of symbols of each length */
    short *symbol;      /* canonically ordered symbols */
};

/*
 * Decode a code from the stream s using huffman table h.  Return the symbol or
 * a negative value if there is an error.  If all of the lengths are zero, i.e.
 * an empty code, or if the code is incomplete and an invalid code is received,
 * then -10 is returned after reading MAXBITS bits.
 *
 * Format notes:
 *
 * - The codes as stored in the compressed data are bit-reversed relative to
 *   a simple integer ordering of codes of the same lengths.  Hence below the
 *   bits are pulled from the compressed data one at a time and used to
 *   build the code value reversed from what is in the stream in order to
 *   permit simple integer comparisons for decoding.  A table-based decoding
 *   scheme (as used in zlib) does not need to do this reversal.
 *
 * - The first code for the shortest length is all zeros.  Subsequent codes of
 *   the same length are simply integer increments of the previous code.  When
 *   moving up a length, a zero bit is appended to the code.  For a complete
 *   code, the last code of the longest length will be all ones.
 *
 * - Incomplete codes are handled by this decoder, since they are permitted
 *   in the deflate format.  See the format notes for fixed() and dynamic().

/*
 * Given the list of code lengths length[0..n-1] representing a canonical
 * Huffman code for n symbols, construct the tables required to decode those
 * codes.  Those tables are the number of codes of each length, and the symbols
 * sorted by length, retaining their original order within each length.  The
 * return value is zero for a complete code set, negative for an over-
 * subscribed code set, and positive for an incomplete code set.  The tables
 * can be used if the return value is zero or positive, but they cannot be used
 * if the return value is negative.  If the return value is zero, it is not
 * possible for decode() using that table to return an error--any stream of
 * enough bits will resolve to a symbol.  If the return value is positive, then
 * it is possible for decode() using that table to return an error for received
 * codes past the end of the incomplete lengths.
 *
 * Not used by decode(), but used for error checking, h->count[0] is the number
 * of the n symbols not in the code.  So n - h->count[0] is the number of
 * codes.  This is useful for checking for incomplete codes that have more than
```

```
 * one symbol, which is an error in a dynamic block.
 *
 * Assumption: for all i in 0..n-1, 0 <= length[i] <= MAXBITS
 * This is assured by the construction of the length arrays in dynamic() and
 * fixed() and is not verified by construct().
 *
 * Format notes:
 *
 * - Permitted and expected examples of incomplete codes are one of the fixed
 *   codes and any code with a single symbol which in deflate is coded as one
 *   bit instead of zero bits.  See the format notes for fixed() and dynamic().
 *
 * - Within a given code length, the symbols are kept in ascending order for
 *   the code bits definition.

/*
 * Decode literal/length and distance codes until an end-of-block code.
 *
 * Format notes:
 *
 * - Compressed data that is after the block type if fixed or after the code
 *   description if dynamic is a combination of literals and length/distance
 *   pairs terminated by and end-of-block code.  Literals are simply Huffman
 *   coded bytes.  A length/distance pair is a coded length followed by a
 *   coded distance to represent a string that occurs earlier in the
```

```
 *   uncompressed data that occurs again at the current location.
 *
 * - Literals, lengths, and the end-of-block code are combined into a single
 *   code of up to 286 symbols.  They are 256 literals (0..255), 29 length
 *   symbols (257..285), and the end-of-block symbol (256).
 *
 * - There are 256 possible lengths (3..258), and so 29 symbols are not enough
 *   to represent all of those.  Lengths 3..10 and 258 are in fact represented
 *   by just a length symbol.  Lengths 11..257 are represented as a symbol and
 *   some number of extra bits that are added as an integer to the base length
 *   of the length symbol.  The number of extra bits is determined by the base
 *   length symbol.  These are in the static arrays below, lens[] for the base
 *   lengths and lext[] for the corresponding number of extra bits.
 *
 * - The reason that 258 gets its own symbol is that the longest length is used
 *   often in highly redundant files.  Note that 258 can also be coded as the
 *   base value 227 plus the maximum extra value of 31.  While a good deflate
 *   should never do this, it is not an error, and should be decoded properly.
 *
 * - If a length is decoded, including its extra bits if any, then it is
 *   followed a distance code.  There are up to 30 distance symbols.  Again
 *   there are many more possible distances (1..32768), so extra bits are added
 *   to a base value represented by the symbol.  The distances 1..4 get their
 *   own symbol, but the rest require extra bits.  The base distances and
 *   corresponding number of extra bits are below in the static arrays dist[]
 *   and dext[].
 *
 * - Literal bytes are simply written to the output.  A length/distance pair is
 *   an instruction to copy previously uncompressed bytes to the output.  The
 *   copy is from distance bytes back in the output stream, copying for length
 *   bytes.
 *
 * - Distances pointing before the beginning of the output data are not
 *   permitted.
 *
 * - Overlapped copies, where the length is greater than the distance, are
 *   allowed and common.  For example, a distance of one and a length of 258
 *   simply copies the last byte 258 times.  A distance of four and a length of
 *   twelve copies the last four bytes three times.  A simple forward copy
 *   ignoring whether the length is greater than the distance or not implements
 *   this correctly.  You should not use memcpy() since its behavior is not
 *   defined for overlapped arrays.  You should not use memmove() or bcopy()
 *   since though their behavior -is- defined for overlapping arrays, it is
 *   defined to do the wrong thing in this case.

 * Process a fixed codes block.
 *
 * Format notes:
 *
 * - This block type can be useful for compressing small amounts of data for
 *   which the size of the code descriptions in a dynamic block exceeds the
 *   benefit of custom codes for that block.  For fixed codes, no bits are
 *   spent on code descriptions.  Instead the code lengths for literal/length
 *   codes and distance codes are fixed.  The specific lengths for each symbol
 *   can be seen in the "for" loops below.
```

```
 *
 * - The literal/length code is complete, but has two symbols that are invalid
 *   and should result in an error if received.  This cannot be implemented
 *   simply as an incomplete code since those two symbols are in the "middle"
 *   of the code.  They are eight bits long and the longest literal/length\
 *   code is nine bits.  Therefore the code must be constructed with those
 *   symbols, and the invalid symbols must be detected after decoding.
 *
 * - The fixed distance codes also have two invalid symbols that should result
 *   in an error if received.  Since all of the distance codes are the same
 *   length, this can be implemented as an incomplete code.  Then the invalid
 *   codes are detected while decoding.

/*
 * Process a dynamic codes block.
 *
 * Format notes:
 *
 * - A dynamic block starts with a description of the literal/length and
 *   distance codes for that block.  New dynamic blocks allow the compressor to
 *   rapidly adapt to changing data with new codes optimized for that data.
 *
 * - The codes used by the deflate format are "canonical", which means that
 *   the actual bits of the codes are generated in an unambiguous way simply
```

```
 *   from the number of bits in each code.  Therefore the code descriptions
 *   are simply a list of code lengths for each symbol.
 *
 * - The code lengths are stored in order for the symbols, so lengths are
 *   provided for each of the literal/length symbols, and for each of the
 *   distance symbols.
 *
 * - If a symbol is not used in the block, this is represented by a zero as
 *   as the code length.  This does not mean a zero-length code, but rather
 *   that no code should be created for this symbol.  There is no way in the
 *   deflate format to represent a zero-length code.
 *
 * - The maximum number of bits in a code is 15, so the possible lengths for
 *   any code are 1..15.
 *
 * - The fact that a length of zero is not permitted for a code has an
 *   interesting consequence.  Normally if only one symbol is used for a given
 *   code, then in fact that code could be represented with zero bits.  However
 *   in deflate, that code has to be at least one bit.  So for example, if
 *   only a single distance base symbol appears in a block, then it will be
 *   represented by a single code of length one, in particular one 0 bit.  This
 *   is an incomplete code, since if a 1 bit is received, it has no meaning,
 *   and should result in an error.  So incomplete distance codes of one symbol
 *   should be permitted, and the receipt of invalid codes should be handled.
 *
 * - It is also possible to have a single literal/length code, but that code
 *   must be the end-of-block code, since every dynamic block has one.  This
 *   is not the most efficient way to create an empty block (an empty fixed
 *   block is fewer bits), but it is allowed by the format.  So incomplete
 *   literal/length codes of one symbol should also be permitted.
 *
 * - If there are only literal codes and no lengths, then there are no distance
 *   codes.  This is represented by one distance code with zero bits.
 *
 * - The list of up to 286 length/literal lengths and up to 30 distance lengths
 *   are themselves compressed using Huffman codes and run-length encoding.  In
 *   the list of code lengths, a 0 symbol means no code, a 1..15 symbol means
 *   that length, and the symbols 16, 17, and 18 are run-length instructions.
 *   Each of 16, 17, and 18 are follwed by extra bits to define the length of
 *   the run.  16 copies the last length 3 to 6 times.  17 represents 3 to 10
 *   zero lengths, and 18 represents 11 to 138 zero lengths.  Unused symbols
 *   are common, hence the special coding for zero lengths.
 *
 * - The symbols for 0..18 are Huffman coded, and so that code must be
 *   described first.  This is simply a sequence of up to 19 three-bit values
 *   representing no code (0) or the code length for that symbol (1..7).
 *
 * - A dynamic block starts with three fixed-size counts from which is computed
 *   the number of literal/length code lengths, the number of distance code
 *   lengths, and the number of code length code lengths (ok, you come up with
 *   a better name!) in the code descriptions.  For the literal/length and
 *   distance codes, lengths after those provided are considered zero, i.e. no
 *   code.  The code length code lengths are received in a permuted order (see
 *   the order[] array below) to make a short code length code length list more
 *   likely.  As it turns out, very short and very long codes are less likely
 *   to be seen in a dynamic code description, hence what may appear initially
 *   to be a peculiar ordering.
 *
 * - Given the number of literal/length code lengths (nlen) and distance code
 *   lengths (ndist), then they are treated as one long list of nlen + ndist
 *   code lengths.  Therefore run-length coding can and often does cross the
 *   boundary between the two sets of lengths.
 *
 * - So to summarize, the code description at the start of a dynamic block is
 *   three counts for the number of code lengths for the literal/length codes,
 *   the distance codes, and the code length codes.  This is followed by the
```

```
 *   code length code lengths, three bits each.  This is used to construct the
 *   code length code which is used to read the remainder of the lengths.  Then
 *   the literal/length code lengths and distance lengths are read as a single
 *   set of lengths using the code length codes.  Codes are constructed from
 *   the resulting two sets of lengths, and then finally you can start
 *   decoding actual compressed data in the block.
 *
 * - For reference, a "typical" size for the code description in a dynamic
 *   block is around 80 bytes.

/*
 * Inflate source to dest.  On return, destlen and sourcelen are updated to the
 * size of the uncompressed data and the size of the deflate data respectively.
 * On success, the return value of puff() is zero.  If there is an error in the
 * source data, i.e. it is not in the deflate format, then a negative value is
 * returned.  If there is not enough input available or there is not enough
 * output space, then a positive error is returned.  In that case, destlen and
 * sourcelen are not updated to facilitate retrying from the beginning with the
 * provision of more input data or more output space.  In the case of invalid
 * inflate data (a negative error), the dest and source pointers are updated to
 * facilitate the debugging of deflators.
 *
 * puff() also has a mode to determine the size of the uncompressed output with
 * no output written.  For this dest must be (unsigned char *)0.  In this case,
 * the input value of *destlen is ignored, and on return *destlen is set to the
 * size of the uncompressed output.
 *
 * The return codes are:
 *
 *   2:  available inflate data did not terminate
 *   1:  output space exhausted before completing inflate
 *   0:  successful inflate
 *  -1:  invalid block type (type == 3)
 *  -2:  stored block length did not match one's complement
 *  -3:  dynamic block code description: too many length or distance codes
 *  -4:  dynamic block code description: code lengths codes incomplete
 *  -5:  dynamic block code description: repeat lengths with no first length
 *  -6:  dynamic block code description: repeat more than specified lengths
 *  -7:  dynamic block code description: invalid literal/length code lengths
 *  -8:  dynamic block code description: invalid distance code lengths
 *  -9:  dynamic block code description: missing end-of-block code
 * -10:  invalid literal/length or distance code in fixed or dynamic block
 * -11:  distance is too far back in fixed or dynamic block
 *
 * Format notes:
 *
 * - Three bits are read for each block to determine the kind of block and
 *   whether or not it is the last block.  Then the block is decoded and the
```

```
 *   process repeated if it was not the last block.
 *
 * - The leftover bits in the last byte of the deflate data after the last
 *   block (if it was a fixed or dynamic block) are undefined and have no
 *   expected values to check.

To build testzLib with Visual Studio 2005:

copy to a directory file from :
- root of zLib tree
- contrib/testzlib
- contrib/masmx86
- contrib/masmx64
- contrib/vstudio/vc7

and open testzlib8.sln
```

Building instructions for the DLL versions of Zlib 1.2.8
========================================================

This directory contains projects that build zlib and minizip using
Microsoft Visual C++ 9.0/10.0.

You don't need to build these projects yourself. You can download the
binaries from:
  http://www.winimage.com/zLibDll

More information can be found at this site.

Build instructions for Visual Studio 2008 (32 bits or 64 bits)
--------------------------------------------------------------
- Uncompress current zlib, including all contrib/* files
- Compile assembly code (with Visual Studio Command Prompt) by running:
   bld_ml64.bat (in contrib\masmx64)
   bld_ml32.bat (in contrib\masmx86)
- Open contrib\vstudio\vc9\zlibvc.sln with Microsoft Visual C++ 2008
- Or run: vcbuild /rebuild contrib\vstudio\vc9\zlibvc.sln "Release|Win32"

Build instructions for Visual Studio 2010 (32 bits or 64 bits)
--------------------------------------------------------------
- Uncompress current zlib, including all contrib/* files
- Open contrib\vstudio\vc10\zlibvc.sln with Microsoft Visual C++ 2010

Build instructions for Visual Studio 2012 (32 bits or 64 bits)
--------------------------------------------------------------
- Uncompress current zlib, including all contrib/* files
- Open contrib\vstudio\vc11\zlibvc.sln with Microsoft Visual C++ 2012

Important
---------
- To use zlibwapi.dll in your application, you must define the
  macro ZLIB_WINAPI when compiling your application's source files.

Additional notes
----------------
- This DLL, named zlibwapi.dll, is compatible to the old zlib.dll built
  by Gilles Vollant from the zlib 1.1.x sources, and distributed at
    http://www.winimage.com/zLibDll
  It uses the WINAPI calling convention for the exported functions, and
  includes the minizip functionality. If your application needs that
  particular build of zlib.dll, you can rename zlibwapi.dll to zlib.dll.

- The new DLL was renamed because there exist several incompatible
  versions of zlib.dll on the Internet.

- There is also an official DLL build of zlib, named zlib1.dll. This one
  is exporting the functions using the CDECL convention. See the file
  win32\DLL_FAQ.txt found in this zlib distribution.

- There used to be a ZLIB_DLL macro in zlib 1.1.x, but now this symbol
  has a slightly different effect. To avoid compatibility problems, do
```

```
  not define it here.

Gilles Vollant

/*
  Generate tables for a byte-wise 32-bit CRC calculation on the polynomial:
  x^32+x^26+x^23+x^22+x^16+x^12+x^11+x^10+x^8+x^7+x^5+x^4+x^2+x+1.

  Polynomials over GF(2) are represented in binary, one bit per coefficient,
  with the lowest powers in the most significant bit.  Then adding polynomials
  is just exclusive-or, and multiplying a polynomial by x is a right shift by
  one.  If we call the above polynomial p, and represent a byte as the
  polynomial q, also with the lowest power in the most significant bit (so the
  byte 0xb1 is the polynomial x^7+x^3+x+1), then the CRC is (q*x^32) mod p,
  where a mod b means the remainder after dividing a by b.

  This calculation is done using the shift-register method of multiplying and
  taking the remainder.  The register is initialized to zero, and for each
  incoming bit, x^32 is added mod p to the register if the bit is a one (where
  x^32 mod p is p+x^32 = x^26+...+1), and the register is multiplied mod p by
  x (which is shifting right by one and adding x^32 mod p if the bit shifted
  out is a one).  We start with the highest power (least significant bit) of
  q and repeat for all eight bits of q.

  The first table is simply the CRC of all possible eight bit values.  This is
  all the information needed to generate CRCs on data a byte at a time for all
  combinations of CRC register values and incoming bytes.  The remaining tables
  allow for word-at-a-time CRC calculation for both big-endian and little-
  endian machines, where a word is four bytes.

 */

/*
 *  ALGORITHM
 *
 *      The "deflation" process depends on being able to identify portions
 *      of the input text which are identical to earlier input (within a
 *      sliding window trailing behind the input currently being processed).
 *
 *      The most straightforward technique turns out to be the fastest for
 *      most input files: try all possible matches and select the longest.
 *      The key feature of this algorithm is that insertions into the string
 *      dictionary are very simple and thus fast, and deletions are avoided
 *      completely. Insertions are performed at each input character, whereas
 *      string matches are performed only when the previous match ends. So it
 *      is preferable to spend more time in matches to allow very fast string
 *      insertions and avoid deletions. The matching algorithm for small
 *      strings is inspired from that of Rabin & Karp. A brute force approach
 *      is used to find longer strings when a small match has been found.
 *      A similar algorithm is used in comic (by Jan-Mark Wams) and freeze
 *      (by Leonid Broukhis).
 *         A previous version of this file used a more sophisticated algorithm
 *      (by Fiala and Greene) which is guaranteed to run in linear amortized
 *      time, but has a larger average cost, uses more memory and is patented.
 *      However the F&G algorithm may be faster for some highly redundant
 *      files if the parameter max_chain_length (described below) is too large.
 *
 *  ACKNOWLEDGEMENTS
 *
 *      The idea of lazy evaluation of matches is due to Jan-Mark Wams, and
 *      I found it in 'freeze' written by Leonid Broukhis.
 *      Thanks to many people for bug reports and testing.

557  * For the default windowBits of 15 and memLevel of 8, this function returns
558  * a close to exact, as well as small, upper bound on the compressed size.
559  * They are coded as constants here for a reason--if the #define's are
560  * changed, then this function needs to be changed as well.  The return
561  * value for 15 and 8 only works for those exact settings.
562  *
563  * For any setting other than those defaults for windowBits and memLevel,
564  * the value returned is a conservative worst case for the maximum expansion
565  * resulting from using fixed blocks instead of stored blocks, which deflate
566  * can emit on compressed data for some combinations of the parameters.
567  *
568  * This function could be more sophisticated to provide closer upper bounds for
569  * every combination of windowBits and memLevel.  But even the conservative
570  * upper bound of about 14% expansion does not seem onerous for output buffer
571  * allocation.

/*
 *  ALGORITHM
 *
 *      The "deflation" process depends on being able to identify portions
 *      of the input text which are identical to earlier input (within a
 *      sliding window trailing behind the input currently being processed).
 *
 *      The most straightforward technique turns out to be the fastest for
 *      most input files: try all possible matches and select the longest.
 *      The key feature of this algorithm is that insertions into the string
 *      dictionary are very simple and thus fast, and deletions are avoided
 *      completely. Insertions are performed at each input character, whereas
 *      string matches are performed only when the previous match ends. So it
 *      is preferable to spend more time in matches to allow very fast string
 *      insertions and avoid deletions. The matching algorithm for small
 *      strings is inspired from that of Rabin & Karp. A brute force approach
 *      is used to find longer strings when a small match has been found.
 *      A similar algorithm is used in comic (by Jan-Mark Wams) and freeze
 *      (by Leonid Broukhis).
 *         A previous version of this file used a more sophisticated algorithm
 *      (by Fiala and Greene) which is guaranteed to run in linear amortized
 *      time, but has a larger average cost, uses more memory and is patented.
 *      However the F&G algorithm may be faster for some highly redundant
 *      files if the parameter max_chain_length (described below) is too large.
 *
 *  ACKNOWLEDGEMENTS
 *
 *      The idea of lazy evaluation of matches is due to Jan-Mark Wams, and
 *      I found it in 'freeze' written by Leonid Broukhis.
 *      Thanks to many people for bug reports and testing.

550  * For the default windowBits of 15 and memLevel of 8, this function returns
551  * a close to exact, as well as small, upper bound on the compressed size.
552  * They are coded as constants here for a reason--if the #define's are
553  * changed, then this function needs to be changed as well.  The return
554  * value for 15 and 8 only works for those exact settings.
555  *
556  * For any setting other than those defaults for windowBits and memLevel,
557  * the value returned is a conservative worst case for the maximum expansion
558  * resulting from using fixed blocks instead of stored blocks, which deflate
559  * can emit on compressed data for some combinations of the parameters.
560  *
561  * This function could be more sophisticated to provide closer upper bounds for
562  * every combination of windowBits and memLevel.  But even the conservative
563  * upper bound of about 14% expansion does not seem onerous for output buffer
564  * allocation.

221      * limiting lit_bufsize to 64K:
222      *   - frequencies can be kept in 16 bit counters
223      *   - if compression is not successful for the first block, all input
224      *     data is still in the window so we can still emit a stored block even
225      *     when input comes from standard input.  (This can also be done for
226      *     all blocks if lit_bufsize is not greater than 32K.)
227      *   - if compression is not successful for a file smaller than 64K, we can
228      *     even emit a stored file instead of a stored block (saving 5 bytes).
229      *     This is applicable only for zip (not gzip or zlib).
230      *   - creating new Huffman trees less frequently may not provide fast
231      *     adaptation to changes in the input data statistics. (Take for
232      *     example a binary file with poorly compressible code followed by
233      *     a highly compressible string table.) Smaller buffer sizes give
234      *     fast adaptation but have of course the overhead of transmitting
235      *     trees more frequently.

1. Compression algorithm (deflate)

The deflation algorithm used by gzip (also zip and zlib) is a variation of LZ77 (Lempel-Ziv 1977, see reference below). It finds duplicated strings in the input data. The second occurrence of a string is replaced by a pointer to the previous string, in the form of a pair (distance, length). Distances are limited to 32K bytes, and lengths are limited to 258 bytes. When a string does not occur anywhere in the previous 32K bytes, it is emitted as a sequence of literal bytes. (In this description, 'string' must be taken as an arbitrary sequence of bytes, and is not restricted to printable characters.)

Literals or match lengths are compressed with one Huffman tree, and match distances are compressed with another tree. The trees are stored in a compact form at the start of each block. The blocks can have any size (except that the compressed data for one block must fit in available memory). A block is terminated when deflate() determines that it would be useful to start another block with fresh trees. (This is somewhat similar to the behavior of LZW-based _compress_.)

Duplicated strings are found using a hash table. All input strings of length 3 are inserted in the hash table. A hash index is computed for the next 3 bytes. If the hash chain for this index is not empty, all strings in the chain are compared with the current input string, and the longest match is selected.

The hash chains are searched starting with the most recent strings, to favor small distances and thus take advantage of the Huffman encoding. The hash chains are singly linked. There are no deletions from the hash chains, the algorithm simply discards matches that are too old.

To avoid a worst-case situation, very long hash chains are arbitrarily truncated at a certain length, determined by a runtime option (level parameter of deflateInit). So deflate() does not always find the longest possible match but generally finds a match which is long enough.

deflate() also defers the selection of matches with a lazy evaluation mechanism. After a match of length N has been found, deflate() searches for a longer match at the next input byte. If a longer match is found, the previous match is truncated to a length of one (thus producing a single literal byte) and the process of lazy evaluation begins again. Otherwise, the original match is kept, and the next match search is attempted only N steps later.

The lazy match evaluation is also subject to a runtime parameter. If the current match is long enough, deflate() reduces the search for a longer match, thus speeding up the whole process. If compression ratio is more important than speed, deflate() attempts a complete second search even if the first match is already long enough.

The lazy match evaluation is not performed for the fastest compression modes (level parameter 1 to 3). For these fast modes, new strings are inserted in the hash table only when no match was found, or when the match is not too long. This degrades the compression ratio but saves time since there are both fewer insertions and fewer searches.

2. Decompression algorithm (inflate)

2.1 Introduction

The key question is how to represent a Huffman code (or any prefix code) so that you can decode fast. The most important characteristic is that shorter codes are much more common than longer codes, so pay attention to decoding the short codes fast, and let the long codes take longer to decode.

inflate() sets up a first level table that covers some number of bits of input less than the length of longest code. It gets that many bits from the stream, and looks it up in the table. The table will tell if the next code is that many bits or less and how many, and if it is, it will tell the value, else it will point to the next level table for which inflate() grabs more bits and tries to decode a longer code.

How many bits to make the first lookup is a tradeoff between the time it takes to decode and the time it takes to build the table. If building the table took no time (and if you had infinite memory), then there would only be a first level table to cover all the way to the longest code. However, building the table ends up taking a lot longer for more bits since short codes are replicated many times in such a table. What inflate() does is simply to make the number of bits in the first table a variable, and then to set that variable for the maximum speed.

For inflate, which has 286 possible codes for the literal/length tree, the size of the first table is nine bits. Also the distance trees have 30 possible values, and the size of the first table is six bits. Note that for each of those cases, the table ended up one bit longer than the ''average'' code length, i.e. the code length of an approximately flat code which would be a little more than eight bits for 286 symbols and a little less than five bits for 30 symbols.

2.2 More details on the inflate table lookup

Ok, you want to know what this cleverly obfuscated inflate tree actually looks like. You are correct that it's not a Huffman tree. It is simply a lookup table for the first, let's say, nine bits of a Huffman symbol. The symbol could be as short as one bit or as long as 15 bits. If a particular symbol is shorter than nine bits, then that symbol's translation is duplicated in all those entries that start with that symbol's bits. For example, if the symbol is four bits, then it's duplicated 32 times in a nine-bit table. If a symbol is nine bits long, it appears in the table once.

If the symbol is longer than nine bits, then that entry in the table points to another similar table for the remaining bits. Again, there are duplicated entries as needed. The idea is that most of the time the symbol will be short and there will only be one table look up. (That's whole idea behind data compression in the first place.) For the less frequent long symbols, there will be two lookups. If you had a compression method with really long symbols, you could have as many levels of lookups as is efficient. For inflate, two is enough.

So a table entry either points to another table (in which case nine bits in the above example are gobbled), or it contains the translation for the symbol and the number of bits to gobble. Then you start again with the next ungobbled bit.

You may wonder: why not just have one lookup table for how ever many bits the longest symbol is? The reason is that if you do that, you end up spending more time filling in duplicate symbol entries than you do actually decoding. At least for deflate's output that generates new trees every several 10's of kbytes. You can imagine that filling in a 2^15 entry table for a 15-bit code would take too long if you're only decoding several thousand symbols. At the other extreme, you could make a new table for every bit in the code. In fact, that's essentially a Huffman tree. But then you spend too much time traversing the tree while decoding, even for short symbols.

So the number of bits for the first lookup table is a trade of the time to fill out the table vs. the time spent looking at the second level and above of the table.

Here is an example, scaled down:

The code being decoded, with 10 symbols, from 1 to 6 bits long:

```
A: 0
B: 10
C: 1100
D: 11010
E: 11011
F: 11100
G: 11101
H: 11110
I: 111110
J: 111111
```

Let's make the first table three bits long (eight entries):

```
000: A,1
001: A,1
010: A,1
011: A,1
100: B,2
101: B,2
110: -> table X (gobble 3 bits)
111: -> table Y (gobble 3 bits)
```

Each entry is what the bits decode as and how many bits that is, i.e. how many bits to gobble. Or the entry points to another table, with the number of bits to gobble implicit in the size of the table.

Table X is two bits long since the longest code starting with 110 is five bits long:

```
00: C,1
01: C,1
10: D,2
11: E,2
```

Table Y is three bits long since the longest code starting with 111 is six bits long:

```
000: F,2
001: F,2
010: G,2
011: G,2
100: H,2
101: H,2
110: I,3
111: J,3
```

So what we have here are three tables with a total of 20 entries that had to be constructed. That's compared to 64 entries for a single table. Or compared to 16 entries for a Huffman tree (six two entry tables and one four entry table). Assuming that the code ideally represents the probability of the symbols, it takes on the average 1.25 lookups per symbol. That's compared to one lookup for the single table, or 1.66 lookups per symbol for the Huffman tree.

There, I think that gives you a picture of what's going on. For inflate, the meaning of a particular symbol is often more than just a letter. It can be a byte (a "literal"), or it can be either a length or a distance which indicates a base value and a number of bits to fetch after the code that is

added to the base value. Or it might be the special end-of-block code. The data structures created in inftrees.c try to encode all that information compactly in the tables.

ZLIB Compressed Data Format Specification version 3.3

Status of This Memo

This memo provides information for the Internet community. This memo does not specify an Internet standard of any kind. Distribution of this memo is unlimited.

IESG Note:

The IESG takes no position on the validity of any Intellectual Property Rights statements contained in this document.

Notices

A pointer to the latest version of this and related documentation in HTML format can be found at the URL <ftp://ftp.uu.net/graphics/png/documents/zlib/zdoc-index.html>.

Abstract

This specification defines a lossless compressed data format. The data can be produced or consumed, even for an arbitrarily long sequentially presented input data stream, using only an a priori bounded amount of intermediate storage. The format presently uses the DEFLATE compression method but can be easily extended to use other compression methods. It can be implemented readily in a manner not covered by patents. This specification also defines the ADLER-32 checksum (an extension and improvement of the Fletcher checksum), used for detection of data corruption, and provides an algorithm for computing it.

Table of Contents

1. Introduction

1.1. Purpose

The purpose of this specification is to define a lossless compressed data format that:

* Is independent of CPU type, operating system, file system, and character set, and hence can be used for interchange;

* Can be produced or consumed, even for an arbitrarily long sequentially presented input data stream, using only an a priori bounded amount of intermediate storage, and hence can be used in data communications or similar structures such as Unix filters;

* Can use a number of different compression methods;

* Can be implemented readily in a manner not covered by patents, and hence can be practiced freely.

The data format defined by this specification does not attempt to allow random access to compressed data.

1.2. Intended audience

This specification is intended for use by implementors of software to compress data into zlib format and/or decompress data from zlib format.

The text of the specification assumes a basic background in programming at the level of bits and other primitive data representations.

1.3. Scope

The specification specifies a compressed data format that can be used for in-memory compression of a sequence of arbitrary bytes.

1.4. Compliance

Unless otherwise indicated below, a compliant decompressor must be able to accept and decompress any data set that conforms to all the specifications presented here; a compliant compressor must produce data sets that conform to all the specifications presented here.

1.5. Definitions of terms and conventions used

byte: 8 bits stored or transmitted as a unit (same as an octet). (For this specification, a byte is exactly 8 bits, even on machines which store a character on a number of bits different from 8.) See below, for the numbering of bits within a byte.

1.6. Changes from previous versions

Version 3.1 was the first public release of this specification. In version 3.2, some terminology was changed and the Adler-32 sample code was rewritten for clarity. In version 3.3, the support for a preset dictionary was introduced, and the specification was converted to RFC style.

2. Detailed specification

2.1. Overall conventions

In the diagrams below, a box like this:

```
   +---+
   |   | <-- the vertical bars might be missing
   +---+
```

represents one byte; a box like this:

```
   +==============+
   |              |
   +==============+
```

represents a variable number of bytes.

Bytes stored within a computer do not have a "bit order", since they are always treated as a unit. However, a byte considered as an integer between 0 and 255 does have a most- and least-significant bit, and since we write numbers with the most-significant digit on the left, we also write bytes with the most-significant bit on the left. In the diagrams below, we number the bits of a byte so that bit 0 is the least-significant bit, i.e., the bits are numbered:

```
   +--------+
   |76543210|
   +--------+
```

Within a computer, a number may occupy multiple bytes. All multi-byte numbers in the format described here are stored with the MOST-significant byte first (at the lower memory address). For example, the decimal number 520 is stored as:

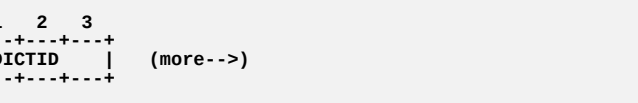
```
        0     1
   +--------+--------+
   |00000010|00001000|
   +--------+--------+
    ^        ^
    |        |
    |        + less significant byte = 8
    + more significant byte = 2 x 256
```

2.2. Data format

A zlib stream has the following structure:

```
     0   1
   +---+---+
   |CMF|FLG|   (more-->)
   +---+---+
```

(if FLG.FDICT set)



Any data which may appear after ADLER32 are not part of the zlib stream.

CMF (Compression Method and flags)
This byte is divided into a 4-bit compression method and a 4-bit information field depending on the compression method.

bits 0 to 3 CM Compression method
bits 4 to 7 CINFO Compression info

CM (Compression method)
This identifies the compression method used in the file. CM = 8 denotes the "deflate" compression method with a window size up to 32K. This is the method used by gzip and PNG (see references [1] and [2] in Chapter 3, below, for the reference documents). CM = 15 is reserved. It might be used in a future version of this specification to indicate the presence of an extra field before the compressed data.

CINFO (Compression info)
For CM = 8, CINFO is the base-2 logarithm of the LZ77 window size, minus eight (CINFO=7 indicates a 32K window size). Values of CINFO above 7 are not allowed in this version of the specification. CINFO is not defined in this specification for CM not equal to 8.

FLG (FLaGs)
This flag byte is divided as follows:

bits 0 to 4 FCHECK (check bits for CMF and FLG)
bit 5 FDICT (preset dictionary)
bits 6 to 7 FLEVEL (compression level)

The FCHECK value must be such that CMF and FLG, when viewed as a 16-bit unsigned integer stored in MSB order (CMF*256 + FLG), is a multiple of 31.

FDICT (Preset dictionary)
If FDICT is set, a DICT dictionary identifier is present immediately after the FLG byte. The dictionary is a sequence of bytes which are initially fed to the compressor without producing any compressed output. DICT is the Adler-32 checksum of this sequence of bytes (see the definition of ADLER32 below). The decompressor can use this identifier to determine which dictionary has been used by the compressor.

FLEVEL (Compression level)
These flags are available for use by specific compression methods. The "deflate" method (CM = 8) sets these flags as follows:

0 - compressor used fastest algorithm
1 - compressor used fast algorithm
2 - compressor used default algorithm
3 - compressor used maximum compression, slowest algorithm

The information in FLEVEL is not needed for decompression; it is there to indicate if recompression might be worthwhile.

compressed data
For compression method 8, the compressed data is stored in the deflate compressed data format as described in the document "DEFLATE Compressed Data Format Specification" by L. Peter Deutsch. (See reference [3] in Chapter 3, below)

Other compressed data formats are not specified in this version of the zlib specification.

ADLER32 (Adler-32 checksum)
This contains a checksum value of the uncompressed data (excluding any dictionary data) computed according to Adler-32 algorithm. This algorithm is a 32-bit extension and improvement of the Fletcher algorithm, used in the ITU-T X.224 / ISO 8073 standard. See references [4] and [5] in Chapter 3, below)

Adler-32 is composed of two sums accumulated per byte: s1 is the sum of all bytes, s2 is the sum of all s1 values. Both sums are done modulo 65521. s1 is initialized to 1, s2 to zero. The Adler-32 checksum is stored as s2*65536 + s1 in most-significant-byte first (network) order.

2.3. Compliance

A compliant compressor must produce streams with correct CMF, FLG and ADLER32, but need not support preset dictionaries. When the zlib data format is used as part of another standard data format, the compressor may use only preset dictionaries that are specified by this other data format. If this other format does not use the preset dictionary feature, the compressor must not set the FDICT flag.

A compliant decompressor must check CMF, FLG, and ADLER32, and provide an error indication if any of these have incorrect values. A compliant decompressor must give an error indication if CM is not one of the values defined in this specification (only the value 8 is permitted in this version), since another value could indicate the presence of new features that would cause subsequent data to be interpreted incorrectly. A compliant decompressor must give an error indication if FDICT is set and DICTID is not the identifier of a known preset dictionary. A decompressor may ignore FLEVEL and still be compliant. When the zlib data format is being used as a part of another standard format, a compliant decompressor must support all the preset dictionaries specified by the other format. When the other format does not use the preset dictionary feature, a compliant decompressor must reject any stream in which the FDICT flag is set.

8. Appendix: Rationale

8.1. Preset dictionaries

A preset dictionary is specially useful to compress short input sequences. The compressor can take advantage of the dictionary context to encode the input in a more compact manner. The decompressor can be initialized with the appropriate context by virtually decompressing a compressed version of the dictionary without producing any output. However for certain compression algorithms such as the deflate algorithm this operation can be achieved without actually performing any decompression.

The compressor and the decompressor must use exactly the same dictionary. The dictionary may be fixed or may be chosen among a certain number of predefined dictionaries, according to the kind of input data. The decompressor can determine which dictionary has been chosen by the compressor by checking the dictionary identifier. This document does not specify the contents of predefined dictionaries, since the optimal dictionaries are application specific. Standard data formats using this feature of the zlib specification must precisely define the allowed dictionaries.

8.2. The Adler-32 algorithm

The Adler-32 algorithm is much faster than the CRC32 algorithm yet still provides an extremely low probability of undetected errors.

The modulo on unsigned long accumulators can be delayed for 5552 bytes, so the modulo operation time is negligible. If the bytes are a, b, c, the second sum is 3a + 2b + c + 3, and so is position and order sensitive, unlike the first sum, which is just a checksum. That 65521 is prime is important to avoid a possible large class of two-byte errors that leave the check unchanged. (The Fletcher checksum uses 255, which is not prime and which also makes the Fletcher check insensitive to single byte changes 0 <-> 255.)

The sum s1 is initialized to 1 instead of zero to make the length of the sequence part of s2, so that the length does not have to be checked separately. (Any sequence of zeroes has a Fletcher checksum of zero.)

9. Appendix: Sample code

The following C code computes the Adler-32 checksum of a data buffer. It is written for clarity, not for speed. The sample code is in the ANSI C programming language. Non C users may find it easier to read with these hints:

```
   &      Bitwise AND operator.
   >>     Bitwise right shift operator. When applied to an
          unsigned quantity, as here, right shift inserts zero bit(s)
          at the left.
   <<     Bitwise left shift operator. Left shift inserts zero
          bit(s) at the right.
   ++     "n++" increments the variable n.
   %      modulo operator: a % b is the remainder of a divided by b.

   #define BASE 65521 /* largest prime smaller than 65536 */

   /*
      Update a running Adler-32 checksum with the bytes buf[0..len-1]
    and return the updated checksum. The Adler-32 checksum should be
    initialized to 1.

    Usage example:

      unsigned long adler = 1L;

      while (read_buffer(buffer, length) != EOF) {
        adler = update_adler32(adler, buffer, length);
      }
      if (adler != original_adler) error();
   */
   unsigned long update_adler32(unsigned long adler,
      unsigned char *buf, int len)
   {
     unsigned long s1 = adler & 0xffff;
     unsigned long s2 = (adler >> 16) & 0xffff;
     int n;

     for (n = 0; n < len; n++) {
       s1 = (s1 + buf[n]) % BASE;
       s2 = (s2 + s1)     % BASE;
     }
     return (s2 << 16) + s1;
   }

   /* Return the adler32 of the bytes buf[0..len-1] */
```

```
      unsigned long adler32(unsigned char *buf, int len)
      {
        return update_adler32(1L, buf, len);
      }
```

```

DEFLATE Compressed Data Format Specification version 1.3

Status of This Memo

This memo provides information for the Internet community. This memo does not specify an Internet standard of any kind. Distribution of this memo is unlimited.

IESG Note:

The IESG takes no position on the validity of any Intellectual Property Rights statements contained in this document.

Notices

A pointer to the latest version of this and related documentation in HTML format can be found at the URL <ftp://ftp.uu.net/graphics/png/documents/zlib/zdoc-index.html>.

Abstract

This specification defines a lossless compressed data format that compresses data using a combination of the LZ77 algorithm and Huffman coding, with efficiency comparable to the best currently available general-purpose compression methods. The data can be produced or consumed, even for an arbitrarily long sequentially presented input data stream, using only an a priori bounded amount of intermediate storage. The format can be implemented readily in a manner not covered by patents.

Table of Contents

1. Introduction

1.1. Purpose

The purpose of this specification is to define a lossless compressed data format that:

* Is independent of CPU type, operating system, file system, and character set, and hence can be used for interchange;
* Can be produced or consumed, even for an arbitrarily long sequentially presented input data stream, using only an a priori bounded amount of intermediate storage, and hence can be used in data communications or similar structures such as Unix filters;
* Compresses data with efficiency comparable to the best currently available general-purpose compression methods, and in particular considerably better than the "compress" program;
* Can be implemented readily in a manner not covered by patents, and hence can be practiced freely;

* Is compatible with the file format produced by the current widely used gzip utility, in that conforming decompressors will be able to read data produced by the existing gzip compressor.

The data format defined by this specification does not attempt to:

* Allow random access to compressed data;
* Compress specialized data (e.g., raster graphics) as well as the best currently available specialized algorithms.

A simple counting argument shows that no lossless compression algorithm can compress every possible input data set. For the format defined here, the worst case expansion is 5 bytes per 32K-byte block, i.e., a size increase of 0.015% for large data sets. English text usually compresses by a factor of 2.5 to 3; executable files usually compress somewhat less; graphical data such as raster images may compress much more.

1.2. Intended audience

This specification is intended for use by implementors of software to compress data into "deflate" format and/or decompress data from "deflate" format.

The text of the specification assumes a basic background in programming at the level of bits and other primitive data representations. Familiarity with the technique of Huffman coding is helpful but not required.

1.3. Scope

The specification specifies a method for representing a sequence of bytes as a (usually shorter) sequence of bits, and a method for packing the latter bit sequence into bytes.

1.4. Compliance

Unless otherwise indicated below, a compliant decompressor must be able to accept and decompress any data set that conforms to all the specifications presented here; a compliant compressor must produce data sets that conform to all the specifications presented here.

1.5. Definitions of terms and conventions used

Byte: 8 bits stored or transmitted as a unit (same as an octet). For this specification, a byte is exactly 8 bits, even on machines

which store a character on a number of bits different from eight. See below, for the numbering of bits within a byte.

String: a sequence of arbitrary bytes.

1.6. Changes from previous versions

There have been no technical changes to the deflate format since version 1.1 of this specification. In version 1.2, some terminology was changed. Version 1.3 is a conversion of the specification to RFC style.

2. Compressed representation overview

A compressed data set consists of a series of blocks, corresponding to successive blocks of input data. The block sizes are arbitrary, except that non-compressible blocks are limited to 65,535 bytes.

Each block is compressed using a combination of the LZ77 algorithm and Huffman coding. The Huffman trees for each block are independent of those for previous or subsequent blocks; the LZ77 algorithm may use a reference to a duplicated string occurring in a previous block, up to 32K input bytes before.

Each block consists of two parts: a pair of Huffman code trees that describe the representation of the compressed data part, and a compressed data part. (The Huffman trees themselves are compressed using Huffman encoding.) The compressed data consists of a series of elements of two types: literal bytes (of strings that have not been detected as duplicated within the previous 32K input bytes), and pointers to duplicated strings, where a pointer is represented as a pair <length, backward distance>. The representation used in the "deflate" format limits distances to 32K bytes and lengths to 258 bytes, but does not limit the size of a block, except for uncompressible blocks, which are limited as noted above.

Each type of value (literals, distances, and lengths) in the compressed data is represented using a Huffman code, using one code tree for literals and lengths and a separate code tree for distances. The code trees for each block appear in a compact form just before the compressed data for that block.

3. Detailed specification

3.1. Overall conventions In the diagrams below, a box like this:

```
   +---+
   |   | <-- the vertical bars might be missing
   +---+
```

represents one byte; a box like this:

```
   +==============+
   |              |
   +==============+
```

represents a variable number of bytes.

Bytes stored within a computer do not have a "bit order", since they are always treated as a unit. However, a byte considered as an integer between 0 and 255 does have a most- and least-significant bit, and since we write numbers with the most-significant digit on the left, we also write bytes with the most-significant bit on the left. In the diagrams below, we number the bits of a byte so that bit 0 is the least-significant bit, i.e., the bits are numbered:

```
   +--------+
   |76543210|
   +--------+
```

Within a computer, a number may occupy multiple bytes. All multi-byte numbers in the format described here are stored with the least-significant byte first (at the lower memory address). For example, the decimal number 520 is stored as:

```
       0       1
   +--------+--------+
   |00001000|00000010|
   +--------+--------+
    ^        ^
    |        |
    |        + more significant byte = 2 x 256
    + less significant byte = 8
```

3.1.1. Packing into bytes

This document does not address the issue of the order in which bits of a byte are transmitted on a bit-sequential medium, since the final data format described here is byte- rather than

bit-oriented. However, we describe the compressed block format in below, as a sequence of data elements of various bit lengths, not a sequence of bytes. We must therefore specify how to pack these data elements into bytes to form the final compressed byte sequence:

* Data elements are packed into bytes in order of increasing bit number within the byte, i.e., starting with the least-significant bit of the byte.
* Data elements other than Huffman codes are packed starting with the least-significant bit of the data element.
* Huffman codes are packed starting with the most-significant bit of the code.

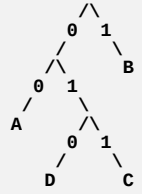
In other words, if one were to print out the compressed data as a sequence of bytes, starting with the first byte at the *right* margin and proceeding to the *left*, with the most-significant bit of each byte on the left as usual, one would be able to parse the result from right to left, with fixed-width elements in the correct MSB-to-LSB order and Huffman codes in bit-reversed order (i.e., with the first bit of the code in the relative LSB position).

3.2. Compressed block format

3.2.1. Synopsis of prefix and Huffman coding

Prefix coding represents symbols from an a priori known alphabet by bit sequences (codes), one code for each symbol, in a manner such that different symbols may be represented by bit sequences of different lengths, but a parser can always parse an encoded string unambiguously symbol-by-symbol.

We define a prefix code in terms of a binary tree in which the two edges descending from each non-leaf node are labeled 0 and 1 and in which the leaf nodes correspond one-for-one with (are labeled with) the symbols of the alphabet; then the code for a symbol is the sequence of 0’s and 1’s on the edges leading from the root to the leaf labeled with that symbol. For example:



Symbol	Code
A	00
B	1
C	011
D	010

A parser can decode the next symbol from an encoded input stream by walking down the tree from the root, at each step choosing the edge corresponding to the next input bit.

Given an alphabet with known symbol frequencies, the Huffman algorithm allows the construction of an optimal prefix code (one which represents strings with those symbol frequencies using the fewest bits of any possible prefix codes for that alphabet). Such a code is called a Huffman code. (See reference [1] in Chapter 5, references for additional information on Huffman codes.)

Note that in the "deflate" format, the Huffman codes for the various alphabets must not exceed certain maximum code lengths. This constraint complicates the algorithm for computing code lengths from symbol frequencies. Again, see Chapter 5, references for details.

3.2.2. Use of Huffman coding in the "deflate" format

The Huffman codes used for each alphabet in the "deflate" format have two additional rules:

* All codes of a given bit length have lexicographically consecutive values, in the same order as the symbols they represent;

* Shorter codes lexicographically precede longer codes.

We could recode the example above to follow this rule as follows, assuming that the order of the alphabet is ABCD:

Symbol	Code
A	10
B	0
C	110
D	111

I.e., 0 precedes 10 which precedes 11x, and 110 and 111 are lexicographically consecutive.

Given this rule, we can define the Huffman code for an alphabet just by giving the bit lengths of the codes for each symbol of the alphabet in order; this is sufficient to determine the actual codes. In our example, the code is completely defined by the sequence of bit lengths (2, 1, 3, 3). The following algorithm generates the codes as integers, intended to be read from most- to least-significant bit. The code lengths are initially in tree[I].Len; the codes are produced in tree[I].Code.

1) Count the number of codes for each code length. Let bl_count[N] be the number of codes of length N, N >= 1.

2) Find the numerical value of the smallest code for each code length:

```
code = 0;
bl_count[0] = 0;
for (bits = 1; bits <= MAX_BITS; bits++) {
    code = (code + bl_count[bits-1]) << 1;
    next_code[bits] = code;
}
```

3) Assign numerical values to all codes, using consecutive values for all codes of the same length with the base values determined at step 2. Codes that are never used (which have a bit length of zero) must not be assigned a value.

```
for (n = 0;  n <= max_code; n++) {
    len = tree[n].Len;
    if (len != 0) {
        tree[n].Code = next_code[len];
        next_code[len]++;
    }
```

```
                }

        Example:

        Consider the alphabet ABCDEFGH, with bit lengths (3, 3, 3, 3,
        3, 2, 4, 4).  After step 1, we have:

           N      bl_count[N]
           -      -----------
           2      1
           3      5
           4      2

        Step 2 computes the following next_code values:

           N      next_code[N]
           -      ------------
           1      0
           2      0
           3      2
           4      14

        Step 3 produces the following code values:

           Symbol Length   Code
           ------ ------   ----
           A       3        010
           B       3        011
           C       3        100
           D       3        101
           E       3        110
           F       2         00
           G       4       1110
           H       4       1111

     3.2.3. Details of block format

        Each block of compressed data begins with 3 header bits
        containing the following data:

           first bit       BFINAL
           next 2 bits     BTYPE

        Note that the header bits do not necessarily begin on a byte
        boundary, since a block does not necessarily occupy an integral
        number of bytes.
```

```
        BFINAL is set if and only if this is the last block of the data
        set.

        BTYPE specifies how the data are compressed, as follows:

           00 - no compression
           01 - compressed with fixed Huffman codes
           10 - compressed with dynamic Huffman codes
           11 - reserved (error)

        The only difference between the two compressed cases is how the
        Huffman codes for the literal/length and distance alphabets are
        defined.

        In all cases, the decoding algorithm for the actual data is as
        follows:

           do
              read block header from input stream.
              if stored with no compression
                 skip any remaining bits in current partially
                    processed byte
                 read LEN and NLEN (see next section)
                 copy LEN bytes of data to output
              otherwise
                 if compressed with dynamic Huffman codes
                    read representation of code trees (see
                       subsection below)
                 loop (until end of block code recognized)
                    decode literal/length value from input stream
                    if value < 256
                       copy value (literal byte) to output stream
                    otherwise
                       if value = end of block (256)
                          break from loop
                       otherwise (value = 257..285)
                          decode distance from input stream

                          move backwards distance bytes in the output
                          stream, and copy length bytes from this
                          position to the output stream.
                 end loop
           while not last block

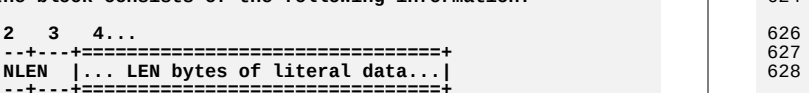
        Note that a duplicated string reference may refer to a string
        in a previous block; i.e., the backward distance may cross one
        or more block boundaries.  However a distance cannot refer past
        the beginning of the output stream.  (An application using a
```

preset dictionary might discard part of the output stream; a distance can refer to that part of the output stream anyway) Note also that the referenced string may overlap the current position; for example, if the last 2 bytes decoded have values X and Y, a string reference with <length = 5, distance = 2> adds X,Y,X,Y,X to the output stream.

We now specify each compression method in turn.

3.2.4. Non-compressed blocks (BTYPE=00)

Any bits of input up to the next byte boundary are ignored. The rest of the block consists of the following information:



LEN is the number of data bytes in the block. NLEN is the one's complement of LEN.

3.2.5. Compressed blocks (length and distance codes)

As noted above, encoded data blocks in the "deflate" format consist of sequences of symbols drawn from three conceptually distinct alphabets: either literal bytes, from the alphabet of byte values (0..255), or <length, backward distance> pairs, where the length is drawn from (3..258) and the distance is drawn from (1..32,768). In fact, the literal and length alphabets are merged into a single alphabet (0..285), where values 0..255 represent literal bytes, the value 256 indicates end-of-block, and values 257..285 represent length codes (possibly in conjunction with extra bits following the symbol code) as follows:

Code	Extra Bits	Length(s)	Code	Extra Bits	Lengths	Code	Extra Bits	Length(s)
257	0	3	267	1	15,16	277	4	67-82
258	0	4	268	1	17,18	278	4	83-98
259	0	5	269	2	19-22	279	4	99-114
260	0	6	270	2	23-26	280	4	115-130
261	0	7	271	2	27-30	281	5	131-162
262	0	8	272	2	31-34	282	5	163-194
263	0	9	273	3	35-42	283	5	195-226
264	0	10	274	3	43-50	284	5	227-257
265	1	11,12	275	3	51-58	285	0	258
266	1	13,14	276	3	59-66			

The extra bits should be interpreted as a machine integer stored with the most-significant bit first, e.g., bits 1110 represent the value 14.

Code	Extra Bits	Dist	Code	Extra Bits	Dist	Code	Extra Bits	Distance
0	0	1	10	4	33-48	20	9	1025-1536
1	0	2	11	4	49-64	21	9	1537-2048
2	0	3	12	5	65-96	22	10	2049-3072
3	0	4	13	5	97-128	23	10	3073-4096
4	1	5,6	14	6	129-192	24	11	4097-6144
5	1	7,8	15	6	193-256	25	11	6145-8192
6	2	9-12	16	7	257-384	26	12	8193-12288
7	2	13-16	17	7	385-512	27	12	12289-16384
8	3	17-24	18	8	513-768	28	13	16385-24576
9	3	25-32	19	8	769-1024	29	13	24577-32768

3.2.6. Compression with fixed Huffman codes (BTYPE=01)

The Huffman codes for the two alphabets are fixed, and are not represented explicitly in the data. The Huffman code lengths for the literal/length alphabet are:

Lit Value	Bits	Codes
0 - 143	8	00110000 through 10111111
144 - 255	9	110010000 through 111111111
256 - 279	7	0000000 through 0010111
280 - 287	8	11000000 through 11000111

The code lengths are sufficient to generate the actual codes, as described above; we show the codes in the table for added clarity. Literal/length values 286-287 will never actually occur in the compressed data, but participate in the code construction.

Distance codes 0-31 are represented by (fixed-length) 5-bit codes, with possible additional bits as shown in the table shown in Paragraph 3.2.5, above. Note that distance codes 30-31 will never actually occur in the compressed data.

3.2.7. Compression with dynamic Huffman codes (BTYPE=10)

The Huffman codes for the two alphabets appear in the block immediately after the header bits and before the actual compressed data, first the literal/length code and then the distance code. Each code is defined by a sequence of code lengths, as discussed in Paragraph 3.2.2, above. For even greater compactness, the code length sequences themselves are compressed using a Huffman code. The alphabet for code lengths is as follows:

```
      0 - 15: Represent code lengths of 0 - 15
          16: Copy the previous code length 3 - 6 times.
              The next 2 bits indicate repeat length
                    (0 = 3, ... , 3 = 6)
                 Example:  Codes 8, 16 (+2 bits 11),
                           16 (+2 bits 10) will expand to
                           12 code lengths of 8 (1 + 6 + 5)
          17: Repeat a code length of 0 for 3 - 10 times.
              (3 bits of length)
          18: Repeat a code length of 0 for 11 - 138 times
              (7 bits of length)
```

A code length of 0 indicates that the corresponding symbol in the literal/length or distance alphabet will not occur in the block, and should not participate in the Huffman code construction algorithm given earlier. If only one distance code is used, it is encoded using one bit, not zero bits; in this case there is a single code length of one, with one unused code. One distance code of zero bits means that there are no distance codes used at all (the data is all literals).

We can now define the format of the block:

```
      5 Bits: HLIT, # of Literal/Length codes - 257 (257 - 286)
      5 Bits: HDIST, # of Distance codes - 1        (1 - 32)
      4 Bits: HCLEN, # of Code Length codes - 4     (4 - 19)
```

```
       (HCLEN + 4) x 3 bits: code lengths for the code length
          alphabet given just above, in the order: 16, 17, 18,
          0, 8, 7, 9, 6, 10, 5, 11, 4, 12, 3, 13, 2, 14, 1, 15

          These code lengths are interpreted as 3-bit integers
          (0-7); as above, a code length of 0 means the
          corresponding symbol (literal/length or distance code
          length) is not used.

       HLIT + 257 code lengths for the literal/length alphabet,
          encoded using the code length Huffman code

       HDIST + 1 code lengths for the distance alphabet,
          encoded using the code length Huffman code

       The actual compressed data of the block,
          encoded using the literal/length and distance Huffman
          codes

       The literal/length symbol 256 (end of data),
          encoded using the literal/length Huffman code
```

The code length repeat codes can cross from HLIT + 257 to the HDIST + 1 code lengths. In other words, all code lengths form a single sequence of HLIT + HDIST + 258 values.

3.3. Compliance

A compressor may limit further the ranges of values specified in the previous section and still be compliant; for example, it may limit the range of backward pointers to some value smaller than 32K. Similarly, a compressor may limit the size of blocks so that a compressible block fits in memory.

A compliant decompressor must accept the full range of possible values defined in the previous section, and must accept blocks of arbitrary size.

4. Compression algorithm details

While it is the intent of this document to define the "deflate" compressed data format without reference to any particular compression algorithm, the format is related to the compressed formats produced by LZ77 (Lempel-Ziv 1977, see reference [2] below); since many variations of LZ77 are patented, it is strongly recommended that the implementor of a compressor follow the general algorithm presented here, which is known not to be patented per se. The material in this section is not part of the definition of the

specification per se, and a compressor need not follow it in order to be compliant.

The compressor terminates a block when it determines that starting a new block with fresh trees would be useful, or when the block size fills up the compressor's block buffer.

The compressor uses a chained hash table to find duplicated strings, using a hash function that operates on 3-byte sequences. At any given point during compression, let XYZ be the next 3 input bytes to be examined (not necessarily all different, of course). First, the compressor examines the hash chain for XYZ. If the chain is empty, the compressor simply writes out X as a literal byte and advances one byte in the input. If the hash chain is not empty, indicating that the sequence XYZ (or, if we are unlucky, some other 3 bytes with the same hash function value) has occurred recently, the compressor compares all strings on the XYZ hash chain with the actual input data sequence starting at the current point, and selects the longest match.

The compressor searches the hash chains starting with the most recent strings, to favor small distances and thus take advantage of the Huffman encoding. The hash chains are singly linked. There are no deletions from the hash chains; the algorithm simply discards matches that are too old. To avoid a worst-case situation, very long hash chains are arbitrarily truncated at a certain length, determined by a run-time parameter.

To improve overall compression, the compressor optionally defers the selection of matches ("lazy matching"): after a match of length N has been found, the compressor searches for a longer match starting at the next input byte. If it finds a longer match, it truncates the previous match to a length of one (thus producing a single literal byte) and then emits the longer match. Otherwise, it emits the original match, and, as described above, advances N bytes before continuing.

Run-time parameters also control this "lazy match" procedure. If compression ratio is most important, the compressor attempts a complete second search regardless of the length of the first match. In the normal case, if the current match is "long enough", the compressor reduces the search for a longer match, thus speeding up the process. If speed is most important, the compressor inserts new strings in the hash table only when no match was found, or when the match is not "too long". This degrades the compression ratio but saves time since there are both fewer insertions and fewer searches.

6. Security Considerations

Any data compression method involves the reduction of redundancy in the data. Consequently, any corruption of the data is likely to have severe effects and be difficult to correct. Uncompressed text, on the other hand, will probably still be readable despite the presence of some corrupted bytes.

It is recommended that systems using this data format provide some means of validating the integrity of the compressed data. See reference [3], for example.

7. Source code

Source code for a C language implementation of a "deflate" compliant compressor and decompressor is available within the zlib package at ftp://ftp.uu.net/pub/archiving/zip/zlib/.

Abstract

This specification defines a lossless compressed data format that is compatible with the widely used GZIP utility. The format includes a cyclic redundancy check value for detecting data corruption. The format presently uses the DEFLATE method of compression but can be easily extended to use other compression methods. The format can be implemented readily in a manner not covered by patents.

Table of Contents

1. Introduction

1.1. Purpose

The purpose of this specification is to define a lossless compressed data format that:

* Is independent of CPU type, operating system, file system, and character set, and hence can be used for interchange;
* Can compress or decompress a data stream (as opposed to a randomly accessible file) to produce another data stream, using only an a priori bounded amount of intermediate storage, and hence can be used in data communications or similar structures such as Unix filters;
* Compresses data with efficiency comparable to the best currently available general-purpose compression methods, and in particular considerably better than the "compress" program;
* Can be implemented readily in a manner not covered by patents, and hence can be practiced freely;
* Is compatible with the file format produced by the current widely used gzip utility, in that conforming decompressors will be able to read data produced by the existing gzip compressor.

The data format defined by this specification does not attempt to:

* Provide random access to compressed data;
* Compress specialized data (e.g., raster graphics) as well as the best currently available specialized algorithms.

1.2. Intended audience

This specification is intended for use by implementors of software to compress data into gzip format and/or decompress data from gzip format.

The text of the specification assumes a basic background in programming at the level of bits and other primitive data representations.

1.3. Scope

The specification specifies a compression method and a file format (the latter assuming only that a file can store a sequence of arbitrary bytes). It does not specify any particular interface to a file system or anything about character sets or encodings (except for file names and comments, which are optional).

1.4. Compliance

Unless otherwise indicated below, a compliant decompressor must be able to accept and decompress any file that conforms to all the specifications presented here; a compliant compressor must produce files that conform to all the specifications presented here. The material in the appendices is not part of the specification per se and is not relevant to compliance.

1.5. Definitions of terms and conventions used

byte: 8 bits stored or transmitted as a unit (same as an octet). (For this specification, a byte is exactly 8 bits, even on machines which store a character on a number of bits different from 8.) See below for the numbering of bits within a byte.

1.6. Changes from previous versions

There have been no technical changes to the gzip format since version 4.1 of this specification. In version 4.2, some terminology was changed, and the sample CRC code was rewritten for clarity and to eliminate the requirement for the caller to do pre- and post-conditioning. Version 4.3 is a conversion of the specification to RFC style.

2. Detailed specification

2.1. Overall conventions

In the diagrams below, a box like this:

```
+---+
|   | <-- the vertical bars might be missing
+---+
```

represents one byte; a box like this:

```
+==============+
|              |
+==============+
```

represents a variable number of bytes.

Bytes stored within a computer do not have a "bit order", since they are always treated as a unit. However, a byte considered as an integer between 0 and 255 does have a most- and least-significant bit, and since we write numbers with the most-significant digit on the left, we also write bytes with the most-significant bit on the left. In the diagrams below, we number the bits of a byte so that bit 0 is the least-significant bit, i.e., the bits are numbered:

```
+--------+
|76543210|
+--------+
```

This document does not address the issue of the order in which bits of a byte are transmitted on a bit-sequential medium, since the data format described here is byte- rather than bit-oriented.

Within a computer, a number may occupy multiple bytes. All multi-byte numbers in the format described here are stored with the least-significant byte first (at the lower memory address). For example, the decimal number 520 is stored as:

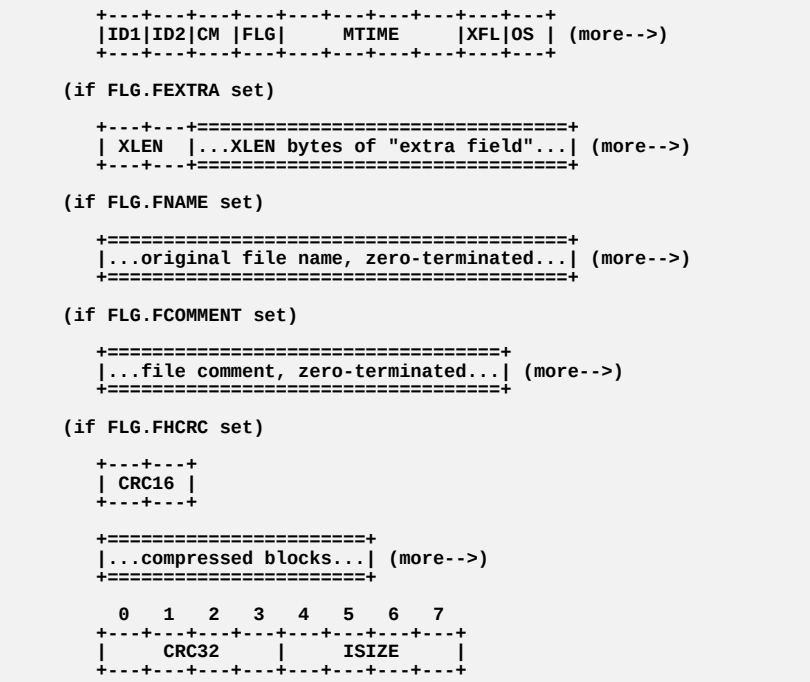
```
      0        1
+--------+--------+
|00001000|00000010|
+--------+--------+
 ^        ^
 |        |
 |        + more significant byte = 2 x 256
 + less significant byte = 8
```

2.2. File format

A gzip file consists of a series of "members" (compressed data sets). The format of each member is specified in the following section. The members simply appear one after another in the file, with no additional information before, between, or after them.

2.3. Member format

Each member has the following structure:



2.3.1. Member header and trailer

ID1 (IDentification 1)
ID2 (IDentification 2)
These have the fixed values ID1 = 31 (0x1f, \037), ID2 = 139 (0x8b, \213), to identify the file as being in gzip format.

CM (Compression Method)
This identifies the compression method used in the file. CM = 0-7 are reserved. CM = 8 denotes the "deflate" compression method, which is the one customarily used by gzip and which is documented elsewhere.

FLG (FLaGs)
This flag byte is divided into individual bits as follows:

bit 0 FTEXT
bit 1 FHCRC
bit 2 FEXTRA
bit 3 FNAME
bit 4 FCOMMENT
bit 5 reserved
bit 6 reserved
bit 7 reserved

If FTEXT is set, the file is probably ASCII text. This is an optional indication, which the compressor may set by checking a small amount of the input data to see whether any non-ASCII characters are present. In case of doubt, FTEXT is cleared, indicating binary data. For systems which have different file formats for ascii text and binary data, the decompressor can use FTEXT to choose the appropriate format. We deliberately do not specify the algorithm used to set this bit, since a compressor always has the option of leaving it cleared and a decompressor always has the option of ignoring it and letting some other program handle issues of data conversion.

If FHCRC is set, a CRC16 for the gzip header is present, immediately before the compressed data. The CRC16 consists of the two least significant bytes of the CRC32 for all bytes of the gzip header up to and not including the CRC16. [The FHCRC bit was never set by versions of gzip up to 1.2.4, even though it was documented with a different meaning in gzip 1.2.4.]

If FEXTRA is set, optional extra fields are present, as described in a following section.

If FNAME is set, an original file name is present, terminated by a zero byte. The name must consist of ISO 8859-1 (LATIN-1) characters; on operating systems using EBCDIC or any other character set for file names, the name must be translated to the ISO LATIN-1 character set. This is the original name of the file being compressed, with any directory components removed, and, if the file being compressed is on a file system with case insensitive names, forced to lower case. There is no original file name if the data was compressed from a source other than a named file; for example, if the source was stdin on a Unix system, there is no file name.

If FCOMMENT is set, a zero-terminated file comment is present. This comment is not interpreted; it is only intended for human consumption. The comment must consist of ISO 8859-1 (LATIN-1) characters. Line breaks should be denoted by a single line feed character (10 decimal).

Reserved FLG bits must be zero.

MTIME (Modification TIME)
This gives the most recent modification time of the original file being compressed. The time is in Unix format, i.e., seconds since 00:00:00 GMT, Jan. 1, 1970. (Note that this may cause problems for MS-DOS and other systems that use local rather than Universal time.) If the compressed data did not come from a file, MTIME is set to the time at which compression started. MTIME = 0 means no time stamp is available.

XFL (eXtra FLags)
These flags are available for use by specific compression methods. The "deflate" method (CM = 8) sets these flags as follows:

XFL = 2 - compressor used maximum compression, slowest algorithm
XFL = 4 - compressor used fastest algorithm

OS (Operating System)
This identifies the type of file system on which compression took place. This may be useful in determining end-of-line convention for text files. The currently defined values are as follows:

0 - FAT filesystem (MS-DOS, OS/2, NT/Win32)
1 - Amiga
2 - VMS (or OpenVMS)
3 - Unix
4 - VM/CMS
5 - Atari TOS
6 - HPFS filesystem (OS/2, NT)
7 - Macintosh
8 - Z-System
9 - CP/M
10 - TOPS-20
11 - NTFS filesystem (NT)
12 - QDOS
13 - Acorn RISCOS
255 - unknown

XLEN (eXtra LENgth)
If FLG.FEXTRA is set, this gives the length of the optional extra field. See below for details.

CRC32 (CRC-32)
This contains a Cyclic Redundancy Check value of the uncompressed data computed according to CRC-32 algorithm used in the ISO 3309 standard and in section 8.1.1.6.2 of ITU-T recommendation V.42. (See http://www.iso.ch for ordering ISO documents. See gopher://info.itu.ch for an online version of ITU-T V.42.)

ISIZE (Input SIZE)
This contains the size of the original (uncompressed) input data modulo 2^32.

2.3.1.1. Extra field

If the FLG.FEXTRA bit is set, an "extra field" is present in the header, with total length XLEN bytes. It consists of a series of subfields, each of the form:

SI1 and SI2 provide a subfield ID, typically two ASCII letters with some mnemonic value. Jean-Loup Gailly <gzip@prep.ai.mit.edu> is maintaining a registry of subfield IDs; please send him any subfield ID you wish to use. Subfield IDs with SI2 = 0 are reserved for future use. The following IDs are currently defined:

SI1	SI2	Data
0x41 (’A’)	0x70 (’P’)	Apollo file type information

LEN gives the length of the subfield data, excluding the 4 initial bytes.

2.3.1.2. Compliance

A compliant compressor must produce files with correct ID1, ID2, CM, CRC32, and ISIZE, but may set all the other fields in the fixed-length part of the header to default values (255 for OS, 0 for all others). The compressor must set all reserved bits to zero.

A compliant decompressor must check ID1, ID2, and CM, and provide an error indication if any of these have incorrect values. It must examine FEXTRA/XLEN, FNAME, FCOMMENT and FHCRC at least so it can skip over the optional fields if they are present. It need not examine any other part of the header or trailer; in particular, a decompressor may ignore FTEXT and OS and always produce binary output, and still be compliant. A compliant decompressor must give an error indication if any reserved bit is non-zero, since such a bit could indicate the presence of a new field that would cause subsequent data to be interpreted incorrectly.

4. Security Considerations

Any data compression method involves the reduction of redundancy in the data. Consequently, any corruption of the data is likely to have severe effects and be difficult to correct. Uncompressed text, on the other hand, will probably still be readable despite the presence of some corrupted bytes.

It is recommended that systems using this data format provide some means of validating the integrity of the compressed data, such as by setting and checking the CRC-32 check value.

7. Appendix: Jean-Loup Gailly's gzip utility

The most widely used implementation of gzip compression, and the original documentation on which this specification is based, were created by Jean-Loup Gailly <gzip@prep.ai.mit.edu>. Since this implementation is a de facto standard, we mention some more of its features here. Again, the material in this section is not part of the specification per se, and implementations need not follow it to be compliant.

When compressing or decompressing a file, gzip preserves the protection, ownership, and modification time attributes on the local file system, since there is no provision for representing protection attributes in the gzip file format itself. Since the file format includes a modification time, the gzip decompressor provides a command line switch that assigns the modification time from the file, rather than the local modification time of the compressed input, to the decompressed output.

8. Appendix: Sample CRC Code

The following sample code represents a practical implementation of the CRC (Cyclic Redundancy Check). (See also ISO 3309 and ITU-T V.42 for a formal specification.)

The sample code is in the ANSI C programming language. Non C users may find it easier to read with these hints:

```
   &      Bitwise AND operator.
   ^      Bitwise exclusive-OR operator.
   >>     Bitwise right shift operator. When applied to an
          unsigned quantity, as here, right shift inserts zero
          bit(s) at the left.
   !      Logical NOT operator.
   ++     "n++" increments the variable n.
   0xNNN  0x introduces a hexadecimal (base 16) constant.
          Suffix L indicates a long value (at least 32 bits).

   /* Table of CRCs of all 8-bit messages. */
   unsigned long crc_table[256];

   /* Flag: has the table been computed? Initially false. */
   int crc_table_computed = 0;

   /* Make the table for a fast CRC. */
   void make_crc_table(void)
   {
     unsigned long c;
```

```
   int n, k;
   for (n = 0; n < 256; n++) {
     c = (unsigned long) n;
     for (k = 0; k < 8; k++) {
       if (c & 1) {
         c = 0xedb88320L ^ (c >> 1);
       } else {
         c = c >> 1;
       }
     }
     crc_table[n] = c;
   }
   crc_table_computed = 1;
 }

 /*
    Update a running crc with the bytes buf[0..len-1] and return
  the updated crc. The crc should be initialized to zero. Pre- and
  post-conditioning (one's complement) is performed within this
  function so it shouldn't be done by the caller. Usage example:

    unsigned long crc = 0L;

    while (read_buffer(buffer, length) != EOF) {
      crc = update_crc(crc, buffer, length);
    }
    if (crc != original_crc) error();
 */
 unsigned long update_crc(unsigned long crc,
                 unsigned char *buf, int len)
 {
   unsigned long c = crc ^ 0xffffffffL;
   int n;

   if (!crc_table_computed)
     make_crc_table();
   for (n = 0; n < len; n++) {
     c = crc_table[(c ^ buf[n]) & 0xff] ^ (c >> 8);
   }
   return c ^ 0xffffffffL;
 }

 /* Return the CRC of the bytes buf[0..len-1]. */
 unsigned long crc(unsigned char *buf, int len)
 {
   return update_crc(0L, buf, len);
 }
```

```

```
A Fast Method for Identifying Plain Text Files
==============================================

Introduction
------------

Given a file coming from an unknown source, it is sometimes desirable
to find out whether the format of that file is plain text.  Although
this may appear like a simple task, a fully accurate detection of the
file type requires heavy-duty semantic analysis on the file contents.
It is, however, possible to obtain satisfactory results by employing
various heuristics.

Previous versions of PKZip and other zip-compatible compression tools
were using a crude detection scheme: if more than 80% (4/5) of the bytes
found in a certain buffer are within the range [7..127], the file is
labeled as plain text, otherwise it is labeled as binary.  A prominent
limitation of this scheme is the restriction to Latin-based alphabets.
Other alphabets, like Greek, Cyrillic or Asian, make extensive use of
the bytes within the range [128..255], and texts using these alphabets
are most often misidentified by this scheme; in other words, the rate
of false negatives is sometimes too high, which means that the recall
is low.  Another weakness of this scheme is a reduced precision, due to
the false positives that may occur when binary files containing large
amounts of textual characters are misidentified as plain text.

In this article we propose a new, simple detection scheme that features
a much increased precision and a near-100% recall.  This scheme is
designed to work on ASCII, Unicode and other ASCII-derived alphabets,
and it handles single-byte encodings (ISO-8859, MacRoman, KOI8, etc.)
and variable-sized encodings (ISO-2022, UTF-8, etc.).  Wider encodings
(UCS-2/UTF-16 and UCS-4/UTF-32) are not handled, however.

The Algorithm
-------------

The algorithm works by dividing the set of bytecodes [0..255] into three
categories:
- The white list of textual bytecodes:
  9 (TAB), 10 (LF), 13 (CR), 32 (SPACE) to 255.
- The gray list of tolerated bytecodes:
  7 (BEL), 8 (BS), 11 (VT), 12 (FF), 26 (SUB), 27 (ESC).
- The black list of undesired, non-textual bytecodes:
  0 (NUL) to 6, 14 to 31.

If a file contains at least one byte that belongs to the white list and
no byte that belongs to the black list, then the file is categorized as
plain text; otherwise, it is categorized as binary.  (The boundary case,
when the file is empty, automatically falls into the latter category.)

Rationale
---------

The idea behind this algorithm relies on two observations.

The first observation is that, although the full range of 7-bit codes
[0..127] is properly specified by the ASCII standard, most control
```

```
characters in the range [0..31] are not used in practice.  The only
widely-used, almost universally-portable control codes are 9 (TAB),
10 (LF) and 13 (CR).  There are a few more control codes that are
recognized on a reduced range of platforms and text viewers/editors:
7 (BEL), 8 (BS), 11 (VT), 12 (FF), 26 (SUB) and 27 (ESC); but these
codes are rarely (if ever) used alone, without being accompanied by
some printable text.  Even the newer, portable text formats such as
XML avoid using control characters outside the list mentioned here.

The second observation is that most of the binary files tend to contain
control characters, especially 0 (NUL).  Even though the older text
detection schemes observe the presence of non-ASCII codes from the range
[128..255], the precision rarely has to suffer if this upper range is
labeled as textual, because the files that are genuinely binary tend to
contain both control characters and codes from the upper range.  On the
other hand, the upper range needs to be labeled as textual, because it
is used by virtually all ASCII extensions.  In particular, this range is
used for encoding non-Latin scripts.

Since there is no counting involved, other than simply observing the
presence or the absence of some byte values, the algorithm produces
consistent results, regardless what alphabet encoding is being used.
(If counting were involved, it could be possible to obtain different
results on a text encoded, say, using ISO-8859-16 versus UTF-8.)

There is an extra category of plain text files that are "polluted" with
one or more black-listed codes, either by mistake or by peculiar design
considerations.  In such cases, a scheme that tolerates a small fraction
of black-listed codes would provide an increased recall (i.e. more true
positives).  This, however, incurs a reduced precision overall, since
false positives are more likely to appear in binary files that contain
large chunks of textual data.  Furthermore, "polluted" plain text should
be regarded as binary by general-purpose text detection schemes, because
general-purpose text processing algorithms might not be applicable.
Under this premise, it is safe to say that our detection method provides
a near-100% recall.

Experiments have been run on many files coming from various platforms
and applications.  We tried plain text files, system logs, source code,
formatted office documents, compiled object code, etc.  The results
confirm the optimistic assumptions about the capabilities of this
algorithm.

This directory contains examples of the use of zlib and other relevant
programs and documentation.

enough.c
    calculation and justification of ENOUGH parameter in inftrees.h
    - calculates the maximum table space used in inflate tree
      construction over all possible Huffman codes

fitblk.c
    compress just enough input to nearly fill a requested output size
    - zlib isn't designed to do this, but fitblk does it anyway

gun.c
    uncompress a gzip file
    - illustrates the use of inflateBack() for high speed file-to-file
      decompression using call-back functions
    - is approximately twice as fast as gzip -d
    - also provides Unix uncompress functionality, again twice as fast

gzappend.c
    append to a gzip file
    - illustrates the use of the Z_BLOCK flush parameter for inflate()
    - illustrates the use of deflatePrime() to start at any bit

gzjoin.c
    join gzip files without recalculating the crc or recompressing
    - illustrates the use of the Z_BLOCK flush parameter for inflate()
    - illustrates the use of crc32_combine()

gzlog.c
gzlog.h
    efficiently and robustly maintain a message log file in gzip format
    - illustrates use of raw deflate, Z_PARTIAL_FLUSH, deflatePrime(),
      and deflateSetDictionary()
    - illustrates use of a gzip header extra field

zlib_how.html
    painfully comprehensive description of zpipe.c (see below)
    - describes in excruciating detail the use of deflate() and inflate()

zpipe.c
    reads and writes zlib streams from stdin to stdout
    - illustrates the proper use of deflate() and inflate()
    - deeply commented in zlib_how.html (see above)

zran.c
    index a zlib or gzip stream and randomly access it
    - illustrates the use of Z_BLOCK, inflatePrime(), and
      inflateSetDictionary() to provide random access
```

 */

/*
   Examine all possible Huffman codes for a given number of symbols and a
   maximum code length in bits to determine the maximum table size for zilb's
   inflate.  Only complete Huffman codes are counted.

   Two codes are considered distinct if the vectors of the number of codes per
   length are not identical.  So permutations of the symbol assignments result
   in the same code for the counting, as do permutations of the assignments of
   the bit values to the codes (i.e. only canonical codes are counted).

   We build a code from shorter to longer lengths, determining how many symbols
   are coded at each length.  At each step, we have how many symbols remain to
   be coded, what the last code length used was, and how many bit patterns of
   that length remain unused. Then we add one to the code length and double the
   number of unused patterns to graduate to the next code length.  We then
   assign all portions of the remaining symbols to that code length that
   preserve the properties of a correct and eventually complete code.  Those
   properties are: we cannot use more bit patterns than are available; and when
   all the symbols are used, there are exactly zero possible bit patterns
   remaining.

   The inflate Huffman decoding algorithm uses two-level lookup tables for
   speed.  There is a single first-level table to decode codes up to root bits
   in length (root == 9 in the current inflate implementation).  The table
   has 1 << root entries and is indexed by the next root bits of input.  Codes
   shorter than root bits have replicated table entries, so that the correct
   entry is pointed to regardless of the bits that follow the short code.  If
   the code is longer than root bits, then the table entry points to a second-
   level table.  The size of that table is determined by the longest code with
   that root-bit prefix.  If that longest code has length len, then the table
   has size 1 << (len - root), to index the remaining bits in that set of
   codes.  Each subsequent root-bit prefix then has its own sub-table.  The
   total number of table entries required by the code is calculated
   incrementally as the number of codes at each bit length is populated.  When
   all of the codes are shorter than root bits, then root is reduced to the
   longest code length, resulting in a single, smaller, one-level table.

   The inflate algorithm also provides for small values of root (relative to
   the log2 of the number of symbols), where the shortest code has more bits
```

```
   than root.  In that case, root is increased to the length of the shortest
   code.  This program, by design, does not handle that case, so it is verified
   that the number of symbols is less than 2^(root + 1).

   In order to speed up the examination (by about ten orders of magnitude for
   the default arguments), the intermediate states in the build-up of a code
   are remembered and previously visited branches are pruned.  The memory
   required for this will increase rapidly with the total number of symbols and
   the maximum code length in bits.  However this is a very small price to pay
   for the vast speedup.

   First, all of the possible Huffman codes are counted, and reachable
   intermediate states are noted by a non-zero count in a saved-results array.
   Second, the intermediate states that lead to (root + 1) bit or longer codes
   are used to look at all sub-codes from those junctures for their inflate
   memory usage.  (The amount of memory used is not affected by the number of
   codes of root bits or less in length.)  Third, the visited states in the
   construction of those sub-codes and the associated calculation of the table
   size is recalled in order to avoid recalculating from the same juncture.
   Beginning the code examination at (root + 1) bit codes, which is enabled by
   identifying the reachable nodes, accounts for about six of the orders of
   magnitude of improvement for the default arguments.  About another four
   orders of magnitude come from not revisiting previous states.  Out of
   approximately 2x10^16 possible Huffman codes, only about 2x10^6 sub-codes
   need to be examined to cover all of the possible table memory usage cases
   for the default arguments of 286 symbols limited to 15-bit codes.

   Note that an unsigned long long type is used for counting.  It is quite easy
   to exceed the capacity of an eight-byte integer with a large number of
   symbols and a large maximum code length, so multiple-precision arithmetic
   would need to replace the unsigned long long arithmetic in that case.  This
   program will abort if an overflow occurs.  The big_t type identifies where
   the counting takes place.

   An unsigned long long type is also used for calculating the number of
   possible codes remaining at the maximum length.  This limits the maximum
   code length to the number of bits in a long long minus the number of bits
   needed to represent the symbols in a flat code.  The code_t type identifies
   where the bit pattern counting takes place.
 */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <assert.h>

#define local static

/* special data types */
typedef unsigned long long big_t;   /* type for code counting */
typedef unsigned long long code_t;  /* type for bit pattern counting */
struct tab {                        /* type for been here check */
    size_t len;         /* length of bit vector in char's */
    char *vec;          /* allocated bit vector */
};

/* The array for saving results, num[], is indexed with this triplet:

      syms: number of symbols remaining to code
      left: number of available bit patterns at length len
      len: number of bits in the codes currently being assigned

   Those indices are constrained thusly when saving results:

      syms: 3..totsym (totsym == total symbols to code)
      left: 2..syms - 1, but only the evens (so syms == 8 -> 2, 4, 6)
```

```
      len: 1..max - 1 (max == maximum code length in bits)

   syms == 2 is not saved since that immediately leads to a single code.  left
   must be even, since it represents the number of available bit patterns at
   the current length, which is double the number at the previous length.
   left ends at syms-1 since left == syms immediately results in a single code.
   (left > sym is not allowed since that would result in an incomplete code.)
   len is less than max, since the code completes immediately when len == max.

   The offset into the array is calculated for the three indices with the
   first one (syms) being outermost, and the last one (len) being innermost.
   We build the array with length max-1 lists for the len index, with syms-3
   of those for each symbol.  There are totsym-2 of those, with each one
   varying in length as a function of sym.  See the calculation of index in
   count() for the index, and the calculation of size in main() for the size
   of the array.

   For the deflate example of 286 symbols limited to 15-bit codes, the array
   has 284,284 entries, taking up 2.17 MB for an 8-byte big_t.  More than
   half of the space allocated for saved results is actually used -- not all
   possible triplets are reached in the generation of valid Huffman codes.
 */

/* The array for tracking visited states, done[], is itself indexed identically
   to the num[] array as described above for the (syms, left, len) triplet.
   Each element in the array is further indexed by the (mem, rem) doublet,
   where mem is the amount of inflate table space used so far, and rem is the
   remaining unused entries in the current inflate sub-table.  Each indexed
   element is simply one bit indicating whether the state has been visited or
   not.  Since the ranges for mem and rem are not known a priori, each bit
   vector is of a variable size, and grows as needed to accommodate the visited
   states.  mem and rem are used to calculate a single index in a triangular
   array.  Since the range of mem is expected in the default case to be about
   ten times larger than the range of rem, the array is skewed to reduce the
   memory usage, with eight times the range for mem than for rem.  See the
   calculations for offset and bit in beenhere() for the details.

   For the deflate example of 286 symbols limited to 15-bit codes, the bit
   vectors grow to total approximately 21 MB, in addition to the 4.3 MB done[]
   array itself.

435
436 /*
437    Examine and show the total number of possible Huffman codes for a given
438    maximum number of symbols, initial root table size, and maximum code length
439    in bits -- those are the command arguments in that order.  The default
440    values are 286, 9, and 15 respectively, for the deflate literal/length code.
441    The possible codes are counted for each number of coded symbols from two to
442    the maximum.  The counts for each of those and the total number of codes are
443    shown.  The maximum number of inflate table entires is then calculated
444    across all possible codes.  Each new maximum number of table entries and the
445    associated sub-code (starting at root + 1 == 10 bits) is shown.
446
447    To count and examine Huffman codes that are not length-limited, provide a
448    maximum length equal to the number of symbols minus one.
449
450    For the deflate literal/length code, use "enough".  For the deflate distance
451    code, use "enough 30 6".
452
453    This uses the %llu printf format to print big_t numbers, which assumes that
454    big_t is an unsigned long long.  If the big_t type is changed (for example
455    to a multiple precision type), the method of printing will also need to be
456    updated.

/* Approach to just fitting a requested compressed size:

   fitblk performs three compression passes on a portion of the input
   data in order to determine how much of that input will compress to
   nearly the requested output block size.  The first pass generates
   enough deflate blocks to produce output to fill the requested
   output size plus a specfied excess amount (see the EXCESS define
   below).  The last deflate block may go quite a bit past that, but
   is discarded.  The second pass decompresses and recompresses just
   the compressed data that fit in the requested plus excess sized
   buffer.  The deflate process is terminated after that amount of
   input, which is less than the amount consumed on the first pass.
   The last deflate block of the result will be of a comparable size
   to the final product, so that the header for that deflate block and
   the compression ratio for that block will be about the same as in
   the final product.  The third compression pass decompresses the
   result of the second step, but only the compressed data up to the
   requested size minus an amount to allow the compressed stream to
   complete (see the MARGIN define below).  That will result in a
   final compressed stream whose length is less than or equal to the
   requested size.  Assuming sufficient input and a requested size
   greater than a few hundred bytes, the shortfall will typically be
   less than ten bytes.

   If the input is short enough that the first compression completes
   before filling the requested output size, then that compressed
   stream is return with no recompression.

   EXCESS is chosen to be just greater than the shortfall seen in a
   two pass approach similar to the above.  That shortfall is due to
   the last deflate block compressing more efficiently with a smaller
   header on the second pass.  EXCESS is set to be large enough so
   that there is enough uncompressed data for the second pass to fill
   out the requested size, and small enough so that the final deflate
   block of the second pass will be close in size to the final deflate
   block of the third and final pass.  MARGIN is chosen to be just
   large enough to assure that the final compression has enough room
   to complete in all cases.

/* Version history:
   1.0  16 Feb 2003  First version for testing of inflateBack()
   1.1  21 Feb 2005  Decompress concatenated gzip streams
                     Remove use of "this" variable (C++ keyword)
                     Fix return value for in()
                     Improve allocation failure checking
                     Add typecasting for void * structures
                     Add -h option for command version and usage
                     Add a bunch of comments
   1.2  20 Mar 2005  Add Unix compress (LZW) decompression
                     Copy file attributes from input file to output file
   1.3  12 Jun 2005  Add casts for error messages [Oberhumer]
   1.4   8 Dec 2006  LZW decompression speed improvements
   1.5   9 Feb 2008  Avoid warning in latest version of gcc
   1.6  17 Jan 2010  Avoid signed/unsigned comparison warnings
   1.7  12 Aug 2012  Update for z_const usage in zlib 1.2.8
 */

/*
   gun [ -t ] [ name ... ]

   decompresses the data in the named gzip files.  If no arguments are given,
   gun will decompress from stdin to stdout.  The names must end in .gz, -gz,
   .z, -z, _z, or .Z.  The uncompressed data will be written to a file name
   with the suffix stripped.  On success, the original file is deleted.  On
   failure, the output file is deleted.  For most failures, the command will
   continue to process the remaining names on the command line.  A memory
   allocation failure will abort the command.  If -t is specified, then the
   listed files or stdin will be tested as gzip files for integrity (without
   checking for a proper suffix), no output will be written, and no files
   will be deleted.

   Like gzip, gun allows concatenated gzip streams and will decompress them,
   writing all of the uncompressed data to the output.  Unlike gzip, gun allows
   an empty file on input, and will produce no error writing an empty output
   file.

   gun will also decompress files made by Unix compress, which uses LZW
   compression.  These files are automatically detected by virtue of their
   magic header bytes.  Since the end of Unix compress stream is marked by the
   end-of-file, they cannot be concantenated.  If a Unix compress stream is
   encountered in an input file, it is the last stream in that file.

   Like gunzip and uncompress, the file attributes of the orignal compressed
   file are maintained in the final uncompressed file, to the extent that the
   user permissions allow it.

   On my Mac OS X PowerPC G4, gun is almost twice as fast as gunzip (version
   1.2.4) is on the same file, when gun is linked with zlib 1.2.2.  Also the
   LZW decompression provided by gun is about twice as fast as the standard
   Unix uncompress command.

 * Change history:
 *
 * 1.0  19 Oct 2003     - First version
 * 1.1   4 Nov 2003     - Expand and clarify some comments and notes
 *                      - Add version and copyright to help
 *                      - Send help to stdout instead of stderr
 *                      - Add some preemptive typecasts
 *                      - Add L to constants in lseek() calls
 *                      - Remove some debugging information in error messages
 *                      - Use new data_type definition for zlib 1.2.1
 *                      - Simplfy and unify file operations
 *                      - Finish off gzip file in gztack()
 *                      - Use deflatePrime() instead of adding empty blocks
 *                      - Keep gzip file clean on appended file read errors
 *                      - Use in-place rotate instead of auxiliary buffer
 *                        (Why you ask?  Because it was fun to write!)
 * 1.2  11 Oct 2012     - Fix for proper z_const usage
 *                      - Check for input buffer malloc failure
 */

/*
   gzappend takes a gzip file and appends to it, compressing files from the
   command line or data from stdin.  The gzip file is written to directly, to
   avoid copying that file, in case it's large.  Note that this results in the
   unfriendly behavior that if gzappend fails, the gzip file is corrupted.

   This program was written to illustrate the use of the new Z_BLOCK option of
   zlib 1.2.x's inflate() function.  This option returns from inflate() at each
   block boundary to facilitate locating and modifying the last block bit at
   the start of the final deflate block.  Also whether using Z_BLOCK or not,
   another required feature of zlib 1.2.x is that inflate() now provides the
   number of unusued bits in the last input byte used.  gzappend will not work
   with versions of zlib earlier than 1.2.1.

   gzappend first decompresses the gzip file internally, discarding all but
```

```
   the last 32K of uncompressed data, and noting the location of the last block
   bit and the number of unused bits in the last byte of the compressed data.
   The gzip trailer containing the CRC-32 and length of the uncompressed data
   is verified.  This trailer will be later overwritten.

   Then the last block bit is cleared by seeking back in the file and rewriting
   the byte that contains it.  Seeking forward, the last byte of the compressed
   data is saved along with the number of unused bits to initialize deflate.

   A deflate process is initialized, using the last 32K of the uncompressed
   data from the gzip file to initialize the dictionary.  If the total
   uncompressed data was less than 32K, then all of it is used to initialize
   the dictionary.  The deflate output bit buffer is also initialized with the
   last bits from the original deflate stream.  From here on, the data to
   append is simply compressed using deflate, and written to the gzip file.
   When that is complete, the new CRC-32 and uncompressed length are written
   as the trailer of the gzip file.

/*
   gzjoin takes one or more gzip files on the command line and writes out a
   single gzip file that will uncompress to the concatenation of the
   uncompressed data from the individual gzip files.  gzjoin does this without
   having to recompress any of the data and without having to calculate a new
   crc32 for the concatenated uncompressed data.  gzjoin does however have to
   decompress all of the input data in order to find the bits in the compressed
   data that need to be modified to concatenate the streams.

   gzjoin does not do an integrity check on the input gzip files other than
   checking the gzip header and decompressing the compressed data.  They are
   otherwise assumed to be complete and correct.

   Each joint between gzip files removes at least 18 bytes of previous trailer
   and subsequent header, and inserts an average of about three bytes to the
   compressed data in order to connect the streams.  The output gzip file
   has a minimal ten-byte gzip header with no file name or modification time.

   This program was written to illustrate the use of the Z_BLOCK option of
   inflate() and the crc32_combine() function.  gzjoin will not compile with
   versions of zlib earlier than 1.2.3.

/*
   gzlog provides a mechanism for frequently appending short strings to a gzip
   file that is efficient both in execution time and compression ratio.  The
   strategy is to write the short strings in an uncompressed form to the end of
   the gzip file, only compressing when the amount of uncompressed data has
   reached a given threshold.

   gzlog also provides protection against interruptions in the process due to
   system crashes.  The status of the operation is recorded in an extra field
   in the gzip file, and is only updated once the gzip file is brought to a
   valid state.  The last data to be appended or compressed is saved in an
   auxiliary file, so that if the operation is interrupted, it can be completed
   the next time an append operation is attempted.

   gzlog maintains another auxiliary file with the last 32K of data from the
   compressed portion, which is preloaded for the compression of the subsequent
   data.  This minimizes the impact to the compression ratio of appending.
 */

/*
   Operations Concept:

   Files (log name "foo"):
   foo.gz -- gzip file with the complete log
   foo.add -- last message to append or last data to compress
   foo.dict -- dictionary of the last 32K of data for next compression
   foo.temp -- temporary dictionary file for compression after this one
   foo.lock -- lock file for reading and writing the other files
   foo.repairs -- log file for log file recovery operations (not compressed)

   gzip file structure:
   - fixed-length (no file name) header with extra field (see below)
   - compressed data ending initially with empty stored block
   - uncompressed data filling out originally empty stored block and
     subsequent stored blocks as needed (16K max each)
   - gzip trailer
   - no junk at end (no other gzip streams)

   When appending data, the information in the first three items above plus the
   foo.add file are sufficient to recover an interrupted append operation.  The
   extra field has the necessary information to restore the start of the last
   stored block and determine where to append the data in the foo.add file, as
   well as the crc and length of the gzip data before the append operation.

   The foo.add file is created before the gzip file is marked for append, and
   deleted after the gzip file is marked as complete.  So if the append
   operation is interrupted, the data to add will still be there.  If due to
   some external force, the foo.add file gets deleted between when the append
   operation was interrupted and when recovery is attempted, the gzip file will
   still be restored, but without the appended data.

   When compressing data, the information in the first two items above plus the
   foo.add file are sufficient to recover an interrupted compress operation.
```

```
   The extra field has the necessary information to find the end of the
   compressed data, and contains both the crc and length of just the compressed
   data and of the complete set of data including the contents of the foo.add
   file.

   Again, the foo.add file is maintained during the compress operation in case
   of an interruption.  If in the unlikely event the foo.add file with the data
   to be compressed is missing due to some external force, a gzip file with
   just the previous compressed data will be reconstructed.  In this case, all
   of the data that was to be compressed is lost (approximately one megabyte).
   This will not occur if all that happened was an interruption of the compress
   operation.

   The third state that is marked is the replacement of the old dictionary with
   the new dictionary after a compress operation.  Once compression is
   complete, the gzip file is marked as being in the replace state.  This
   completes the gzip file, so an interrupt after being so marked does not
   result in recompression.  Then the dictionary file is replaced, and the gzip
   file is marked as completed.  This state prevents the possibility of
   restarting compression with the wrong dictionary file.

   All three operations are wrapped by a lock/unlock procedure.  In order to
   gain exclusive access to the log files, first a foo.lock file must be
   exclusively created.  When all operations are complete, the lock is
   released by deleting the foo.lock file.  If when attempting to create the
   lock file, it already exists and the modify time of the lock file is more
   than five minutes old (set by the PATIENCE define below), then the old
   lock file is considered stale and deleted, and the exclusive creation of
   the lock file is retried.  To assure that there are no false assessments
   of the staleness of the lock file, the operations periodically touch the
   lock file to update the modified date.

   Following is the definition of the extra field with all of the information
   required to enable the above append and compress operations and their
   recovery if interrupted.  Multi-byte values are stored little endian
   (consistent with the gzip format).  File pointers are eight bytes long.
   The crc's and lengths for the gzip trailer are four bytes long.  (Note that
   the length at the end of a gzip file is used for error checking only, and
   for large files is actually the length modulo 2^32.)  The stored block
   length is two bytes long.  The gzip extra field two-byte identification is
   "ap" for append.  It is assumed that writing the extra field to the file is
   an "atomic" operation.  That is, either all of the extra field is written
   to the file, or none of it is, if the operation is interrupted right at the
   point of updating the extra field.  This is a reasonable assumption, since
   the extra field is within the first 52 bytes of the file, which is smaller
   than any expected block size for a mass storage device (usually 512 bytes or
   larger).

   Extra field (35 bytes):
   - Pointer to first stored block length -- this points to the two-byte length
     of the first stored block, which is followed by the two-byte, one's
     complement of that length.  The stored block length is preceded by the
     three-bit header of the stored block, which is the actual start of the
     stored block in the deflate format.  See the bit offset field below.
   - Pointer to the last stored block length.  This is the same as above, but
     for the last stored block of the uncompressed data in the gzip file.
     Initially this is the same as the first stored block length pointer.
     When the stored block gets to 16K (see the MAX_STORE define), then a new
     stored block as added, at which point the last stored block length pointer
     is different from the first stored block length pointer.  When they are
     different, the first bit of the last stored block header is eight bits, or
     one byte back from the block length.
   - Compressed data crc and length.  This is the crc and length of the data
     that is in the compressed portion of the deflate stream.  These are used
     only in the event that the foo.add file containing the data to compress is
     lost after a compress operation is interrupted.
```

```
127    - Total data crc and length.  This is the crc and length of all of the data
128      stored in the gzip file, compressed and uncompressed.  It is used to
129      reconstruct the gzip trailer when compressing, as well as when recovering
130      interrupted operations.
131    - Final stored block length.  This is used to quickly find where to append,
132      and allows the restoration of the original final stored block state when
133      an append operation is interrupted.
134    - First stored block start as the number of bits back from the final stored
135      block first length byte.  This value is in the range of 3..10, and is
136      stored as the low three bits of the final byte of the extra field after
137      subtracting three (0..7).  This allows the last-block bit of the stored
138      block header to be updated when a new stored block is added, for the case
139      when the first stored block and the last stored block are the same.  (When
140      they are different, the numbers of bits back is known to be eight.)  This
141      also allows for new compressed data to be appended to the old compressed
142      data in the compress operation, overwriting the previous first stored
143      block, or for the compressed data to be terminated and a valid gzip file
144      reconstructed on the off chance that a compression operation was
145      interrupted and the data to compress in the foo.add file was deleted.
146    - The operation in process.  This is the next two bits in the last byte (the
147      bits under the mask 0x18).  The are interpreted as 0: nothing in process,
148      1: append in process, 2: compress in process, 3: replace in process.
149    - The top three bits of the last byte in the extra field are reserved and
150      are currently set to zero.

152    Main procedure:
153    - Exclusively create the foo.lock file using the O_CREAT and O_EXCL modes of
154      the system open() call.  If the modify time of an existing lock file is
155      more than PATIENCE seconds old, then the lock file is deleted and the
156      exclusive create is retried.
157    - Load the extra field from the foo.gz file, and see if an operation was in
158      progress but not completed.  If so, apply the recovery procedure below.
159    - Perform the append procedure with the provided data.
160    - If the uncompressed data in the foo.gz file is 1MB or more, apply the
161      compress procedure.
162    - Delete the foo.lock file.

164    Append procedure:
165    - Put what to append in the foo.add file so that the operation can be
166      restarted if this procedure is interrupted.
167    - Mark the foo.gz extra field with the append operation in progress.
168    + Restore the original last-block bit and stored block length of the last
169      stored block from the information in the extra field, in case a previous
170      append operation was interrupted.
171    - Append the provided data to the last stored block, creating new stored
172      blocks as needed and updating the stored blocks last-block bits and
173      lengths.
174    - Update the crc and length with the new data, and write the gzip trailer.
175    - Write over the extra field (with a single write operation) with the new
176      pointers, lengths, and crc's, and mark the gzip file as not in process.
177      Though there is still a foo.add file, it will be ignored since nothing
178      is in process.  If a foo.add file is leftover from a previously
179      completed operation, it is truncated when writing new data to it.
180    - Delete the foo.add file.

182    Compress and replace procedures:
183    - Read all of the uncompressed data in the stored blocks in foo.gz and write
184      it to foo.add.  Also write foo.temp with the last 32K of that data to
185      provide a dictionary for the next invocation of this procedure.
186    - Rewrite the extra field marking foo.gz with a compression in process.
187    * If there is no data provided to compress (due to a missing foo.add file
188      when recovering), reconstruct and truncate the foo.gz file to contain
189      only the previous compressed data and proceed to the step after the next
190      one.  Otherwise ...
191    - Compress the data with the dictionary in foo.dict, and write to the
192      foo.gz file starting at the bit immediately following the last previously
```

```
193      compressed block.  If there is no foo.dict, proceed anyway with the
194      compression at slightly reduced efficiency.  (For the foo.dict file to be
195      missing requires some external failure beyond simply the interruption of
196      a compress operation.)  During this process, the foo.lock file is
197      periodically touched to assure that that file is not considered stale by
198      another process before we're done.  The deflation is terminated with a
199      non-last empty static block (10 bits long), that is then located and
200      written over by a last-bit-set empty stored block.
201    - Append the crc and length of the data in the gzip file (previously
202      calculated during the append operations).
203    - Write over the extra field with the updated stored block offsets, bits
204      back, crc's, and lengths, and mark foo.gz as in process for a replacement
205      of the dictionary.
206    @ Delete the foo.add file.
207    - Replace foo.dict with foo.temp.
208    - Write over the extra field, marking foo.gz as complete.

210    Recovery procedure:
211    - If not a replace recovery, read in the foo.add file, and provide that data
212      to the appropriate recovery below.  If there is no foo.add file, provide
213      a zero data length to the recovery.  In that case, the append recovery
214      restores the foo.gz to the previous compressed + uncompressed data state.
215      For the the compress recovery, a missing foo.add file results in foo.gz
216      being restored to the previous compressed-only data state.
217    - Append recovery:
218      - Pick up append at + step above
219    - Compress recovery:
220      - Pick up compress at * step above
221    - Replace recovery:
222      - Pick up compress at @ step above
223    - Log the repair with a date stamp in foo.repairs

   2.2  14 Aug 2012  Clean up signed comparisons
 */

/*
   The gzlog object allows writing short messages to a gzipped log file,
   opening the log file locked for small bursts, and then closing it.  The log
   object works by appending stored (uncompressed) data to the gzip file until
   1 MB has been accumulated.  At that time, the stored data is compressed, and
   replaces the uncompressed data in the file.  The log file is truncated to
   its new size at that time.  After each write operation, the log file is a
   valid gzip file that can decompressed to recover what was written.

   The gzlog operations can be interupted at any point due to an application or
   system crash, and the log file will be recovered the next time the log is
   opened with gzlog_open().
 */

                     Use switch statement for inflate() return values
   1.2   9 Nov 2004  Add assertions to document zlib guarantees
   1.3   6 Apr 2005  Remove incorrect assertion in inf()
   1.4  11 Dec 2005  Add hack to avoid MSDOS end-of-line conversions
                     Avoid some compiler warnings for input and output buffers
 */
</b></pre><!-- -->
We now include the header files for the required definitions.  From
<tt>stdio.h</tt> we use <tt>fopen()</tt>, <tt>fread()</tt>, <tt>fwrite()</tt>,
<tt>feof()</tt>, <tt>ferror()</tt>, and <tt>fclose()</tt> for file i/o, and
<tt>fputs()</tt> for error messages.  From <tt>string.h</tt> we use
<tt>strcmp()</tt> for command line argument processing.
From <tt>assert.h</tt> we use the <tt>assert()</tt> macro.
From <tt>zlib.h</tt>
we use the basic compression functions <tt>deflateInit()</tt>,
<tt>deflate()</tt>, and <tt>deflateEnd()</tt>, and the basic decompression
functions <tt>inflateInit()</tt>, <tt>inflate()</tt>, and
<tt>inflateEnd()</tt>.
<pre><b>
#include &lt;stdio.h&gt;
#include &lt;string.h&gt;
#include &lt;assert.h&gt;
#include "zlib.h"
</b></pre><!-- -->
This is an ugly hack required to avoid corruption of the input and output data o
Windows/MS-DOS systems.  Without this, those systems would assume that the input
files are text, and try to convert the end-of-line characters from one standard
another.  That would corrupt binary data, and in particular would render the com
This sets the input and output to binary which suppresses the end-of-line conver

    z_stream strm;
    unsigned char in[CHUNK];
    unsigned char out[CHUNK];
</b></pre><!-- -->
The first thing we do is to initialize the <em>zlib</em> state for compression u
<tt>deflateInit()</tt>.  This must be done before the first use of <tt>deflate()
The <tt>zalloc</tt>, <tt>zfree</tt>, and <tt>opaque</tt> fields in the <tt>strm<
structure must be initialized before calling <tt>deflateInit()</tt>.  Here they
set to the <em>zlib</em> constant <tt>Z_NULL</tt> to request that <em>zlib</em>
the default memory allocation routines.  An application may also choose to provi
custom memory allocation routines here.  <tt>deflateInit()</tt> will allocate on
order of 256K bytes for the internal state.
(See <a href="zlib_tech.html"><em>zlib Technical Details</em></a>.)
<p>
<tt>deflateInit()</tt> is called with a pointer to the structure to be initializ
the compression level, which is an integer in the range of -1 to 9.  Lower compr
levels result in faster execution, but less compression.  Higher levels result i
greater compression, but slower execution.  The <em>zlib</em> constant Z_DEFAULT
equal to -1,
provides a good compromise between compression and speed and is equivalent to le
Level 0 actually does no compression at all, and in fact expands the data slight
the <em>zlib</em> format (it is not a byte-for-byte copy of the input).
More advanced applications of <em>zlib</em>
may use <tt>deflateInit2()</tt> here instead.  Such an application may want to r
much memory will be used, at some price in compression.  Or it may need to reque
<em>gzip</em> header and trailer instead of a <em>zlib</em> header and trailer,
encoding with no header or trailer at all.
```

```
<p>
We must check the return value of <tt>deflateInit()</tt> against the <em>zlib</e
<tt>Z_OK</tt> to make sure that it was able to
allocate memory for the internal state, and that the provided arguments were val
<tt>deflateInit()</tt> will also check that the version of <em>zlib</em> that th
file came from matches the version of <em>zlib</em> actually linked with the pro
is especially important for environments in which <em>zlib</em> is a shared libr
<p>
Note that an application can initialize multiple, independent <em>zlib</em> stre
operate in parallel.  The state information maintained in the structure allows t
routines to be reentrant.
<pre><b>
    /* allocate deflate state */
    strm.zalloc = Z_NULL;
    strm.zfree = Z_NULL;
    strm.opaque = Z_NULL;
    ret = deflateInit(&amp;strm, level);
    if (ret != Z_OK)
        return ret;
</b></pre><!-- -->
With the pleasantries out of the way, now we can get down to business.  The oute
reads all of the input file and exits at the bottom of the loop once end-of-file
This loop contains the only call of <tt>deflate()</tt>.  So we must make sure th
input data has been processed and that all of the output data has been generated
before we fall out of the loop at the bottom.
<pre><b>
    /* compress until end of file */
    do {
</b></pre>
We start off by reading data from the input file.  The number of bytes read is p
into <tt>avail_in</tt>, and a pointer to those bytes is put into <tt>next_in</tt
check to see if end-of-file on the input has been reached.  If we are at the end
<em>zlib</em> constant <tt>Z_FINISH</tt>, which is later passed to <tt>deflate()
indicate that this is the last chunk of input data to compress.  We need to use
to check for end-of-file as opposed to seeing if fewer than <tt>CHUNK</tt> bytes
reason is that if the input file length is an exact multiple of <tt>CHUNK</tt>,
the fact that we got to the end-of-file, and not know to tell <tt>deflate()</tt>
up the compressed stream.  If we are not yet at the end of the input, then the <
constant <tt>Z_NO_FLUSH</tt> will be passed to <tt>deflate</tt> to indicate that
in the middle of the uncompressed data.
<p>
If there is an error in reading from the input file, the process is aborted with
<tt>deflateEnd()</tt> being called to free the allocated <em>zlib</em> state bef
the error.  We wouldn't want a memory leak, now would we?  <tt>deflateEnd()</tt>
at any time after the state has been initialized.  Once that's done, <tt>deflate
<tt>deflateInit2()</tt>) would have to be called to start a new compression proc
no point here in checking the <tt>deflateEnd()</tt> return code.  The deallocati
<pre><b>
        strm.avail_in = fread(in, 1, CHUNK, source);
        if (ferror(source)) {
            (void)deflateEnd(&amp;strm);
            return Z_ERRNO;
        }
        flush = feof(source) ? Z_FINISH : Z_NO_FLUSH;
        strm.next_in = in;
</b></pre><!-- -->
The inner <tt>do</tt>-loop passes our chunk of input data to <tt>deflate()</tt>,
keeps calling <tt>deflate()</tt> until it is done producing output.  Once there
new output, <tt>deflate()</tt> is guaranteed to have consumed all of the input,
<tt>avail_in</tt> will be zero.
<pre><b>
        /* run deflate() on input until output buffer not full, finish
           compression if all of source has been read in */
        do {
</b></pre>
Output space is provided to <tt>deflate()</tt> by setting <tt>avail_out</tt> to
```

```
of available output bytes and <tt>next_out</tt> to a pointer to that space.
<pre><b>
            strm.avail_out = CHUNK;
            strm.next_out = out;
</b></pre>
Now we call the compression engine itself, <tt>deflate()</tt>.  It takes as many
<tt>avail_in</tt> bytes at <tt>next_in</tt> as it can process, and writes as man
<tt>avail_out</tt> bytes to <tt>next_out</tt>.  Those counters and pointers are
updated past the input data consumed and the output data written.  It is the amo
output space available that may limit how much input is consumed.
Hence the inner loop to make sure that
all of the input is consumed by providing more output space each time.  Since <t
and <tt>next_in</tt> are updated by <tt>deflate()</tt>, we don't have to mess wi
between <tt>deflate()</tt> calls until it's all used up.
<p>
The parameters to <tt>deflate()</tt> are a pointer to the <tt>strm</tt> structur
the input and output information and the internal compression engine state, and
indicating whether and how to flush data to the output.  Normally <tt>deflate</t
several K bytes of input data before producing any output (except for the header
to accumulate statistics on the data for optimum compression.  It will then put
compressed data, and proceed to consume more input before the next burst.  Event
<tt>deflate()</tt>
must be told to terminate the stream, complete the compression with provided inp
write out the trailer check value.  <tt>deflate()</tt> will continue to compress
as the flush parameter is <tt>Z_NO_FLUSH</tt>.  Once the <tt>Z_FINISH</tt> param
<tt>deflate()</tt> will begin to complete the compressed output stream.  However
much output space is provided, <tt>deflate()</tt> may have to be called several
has provided the complete compressed stream, even after it has consumed all of t
parameter must continue to be <tt>Z_FINISH</tt> for those subsequent calls.
<p>
There are other values of the flush parameter that are used in more advanced app
force <tt>deflate()</tt> to produce a burst of output that encodes all of the in
so far, even if it wouldn't have otherwise, for example to control data latency
compressed data.  You can also ask that <tt>deflate()</tt> do that as well as er
that point so that what follows can be decompressed independently, for example f
applications.  Both requests will degrade compression by an amount depending on
requests are made.
<p>
<tt>deflate()</tt> has a return value that can indicate errors, yet we do not ch
not?  Well, it turns out that <tt>deflate()</tt> can do no wrong here.  Let's go
<tt>deflate()</tt>'s return values and dispense with them one by one.  The possi
<tt>Z_OK</tt>, <tt>Z_STREAM_END</tt>, <tt>Z_STREAM_ERROR</tt>, or <tt>Z_BUF_ERRO
is, well, ok.  <tt>Z_STREAM_END</tt> is also ok and will be returned for the las
<tt>deflate()</tt>.  This is already guaranteed by calling <tt>deflate()</tt> wi
until it has no more output.  <tt>Z_STREAM_ERROR</tt> is only possible if the st
initialized properly, but we did initialize it properly.  There is no harm in ch
<tt>Z_STREAM_ERROR</tt> here, for example to check for the possibility that some
other part of the application inadvertently clobbered the memory containing the
<tt>Z_BUF_ERROR</tt> will be explained further below, but
suffice it to say that this is simply an indication that <tt>deflate()</tt> coul
more input or produce more output.  <tt>deflate()</tt> can be called again with
or more available input, which it will be in this code.
<pre><b>
            ret = deflate(&amp;strm, flush);    /* no bad return value */
            assert(ret != Z_STREAM_ERROR);  /* state not clobbered */
</b></pre>
Now we compute how much output <tt>deflate()</tt> provided on the last call, whi
difference between how much space was provided before the call, and how much out
is still available after the call.  Then that data, if any, is written to the ou
We can then reuse the output buffer for the next call of <tt>deflate()</tt>.  Ag
is a file i/o error, we call <tt>deflateEnd()</tt> before returning to avoid a m
<pre><b>
            have = CHUNK - strm.avail_out;
            if (fwrite(out, 1, have, dest) != have || ferror(dest)) {
                (void)deflateEnd(&amp;strm);
                return Z_ERRNO;
```

```
            }
</b></pre>
The inner <tt>do</tt>-loop is repeated until the last <tt>deflate()</tt> call fa
provided output buffer.  Then we know that <tt>deflate()</tt> has done as much a
the provided input, and that all of that input has been consumed.  We can then f
loop and reuse the input buffer.
<p>
The way we tell that <tt>deflate()</tt> has no more output is by seeing that it
the output buffer, leaving <tt>avail_out</tt> greater than zero.  However suppos
<tt>deflate()</tt> has no more output, but just so happened to exactly fill the
<tt>avail_out</tt> is zero, and we can't tell that <tt>deflate()</tt> has done a
As far as we know, <tt>deflate()</tt>
has more output for us.  So we call it again.  But now <tt>deflate()</tt> produc
at all, and <tt>avail_out</tt> remains unchanged as <tt>CHUNK</tt>.  That <tt>de
wasn't able to do anything, either consume input or produce output, and so it re
<tt>Z_BUF_ERROR</tt>.  (See, I told you I'd cover this later.)  However this is
all.  Now we finally have the desired indication that <tt>deflate()</tt> is real
and so we drop out of the inner loop to provide more input to <tt>deflate()</tt>
<p>
With <tt>flush</tt> set to <tt>Z_FINISH</tt>, this final set of <tt>deflate()</t
complete the output stream.  Once that is done, subsequent calls of <tt>deflate(
<tt>Z_STREAM_ERROR</tt> if the flush parameter is not <tt>Z_FINISH</tt>, and do
until the state is reinitialized.
<p>
Some applications of <em>zlib</em> have two loops that call <tt>deflate()</tt>
instead of the single inner loop we have here.  The first loop would call
without flushing and feed all of the data to <tt>deflate()</tt>.  The second loo
<tt>deflate()</tt> with no more
data and the <tt>Z_FINISH</tt> parameter to complete the process.  As you can se
example, that can be avoided by simply keeping track of the current flush state.
<pre><b>
        } while (strm.avail_out == 0);
        assert(strm.avail_in == 0);     /* all input will be used */
</b></pre><!-- -->
Now we check to see if we have already processed all of the input file.  That in
saved in the <tt>flush</tt> variable, so we see if that was set to <tt>Z_FINISH<
then we're done and we fall out of the outer loop.  We're guaranteed to get <tt>
from the last <tt>deflate()</tt> call, since we ran it until the last chunk of i
consumed and all of the output was generated.
<pre><b>
        /* done when last data in file processed */
    } while (flush != Z_FINISH);
    assert(ret == Z_STREAM_END);        /* stream will be complete */
</b></pre><!-- -->
The process is complete, but we still need to deallocate the state to avoid a me
(or rather more like a memory hemorrhage if you didn't do this).  Then
finally we can return with a happy return value.
<pre><b>
    /* clean up and return */
    (void)deflateEnd(&amp;strm);
    return Z_OK;
}
</b></pre><!-- -->
Now we do the same thing for decompression in the <tt>inf()</tt> routine. <tt>in
decompresses what is hopefully a valid <em>zlib</em> stream from the input file
uncompressed data to the output file.  Much of the discussion above for <tt>def(
applies to <tt>inf()</tt> as well, so the discussion here will focus on the diff
the two.
<pre><b>
/* Decompress from file source to file dest until stream ends or EOF.
   inf() returns Z_OK on success, Z_MEM_ERROR if memory could not be
   allocated for processing, Z_DATA_ERROR if the deflate data is
   invalid or incomplete, Z_VERSION_ERROR if the version of zlib.h and
   the version of the library linked do not match, or Z_ERRNO if there
   is an error reading or writing the files. */
int inf(FILE *source, FILE *dest)
```

```
{
</b></pre>
The local variables have the same functionality as they do for <tt>def()</tt>.
only difference is that there is no <tt>flush</tt> variable, since <tt>inflate()
can tell from the <em>zlib</em> stream itself when the stream is complete.
<pre><b>
    int ret;
    unsigned have;
    z_stream strm;
    unsigned char in[CHUNK];
    unsigned char out[CHUNK];
</b></pre><!-- -->
The initialization of the state is the same, except that there is no compression
of course, and two more elements of the structure are initialized.  <tt>avail_in
and <tt>next_in</tt> must be initialized before calling <tt>inflateInit()</tt>.
is because the application has the option to provide the start of the zlib strea
order for <tt>inflateInit()</tt> to have access to information about the compres
method to aid in memory allocation.  In the current implementation of <em>zlib</
(up through versions 1.2.x), the method-dependent memory allocations are deferre
<tt>inflate()</tt> anyway.  However those fields must be initialized since later
of <em>zlib</em> that provide more compression methods may take advantage of thi
In any case, no decompression is performed by <tt>inflateInit()</tt>, so the
<tt>avail_out</tt> and <tt>next_out</tt> fields do not need to be initialized be
<p>
Here <tt>avail_in</tt> is set to zero and <tt>next_in</tt> is set to <tt>Z_NULL<
indicate that no input data is being provided.
<pre><b>
    /* allocate inflate state */
    strm.zalloc = Z_NULL;
    strm.zfree = Z_NULL;
    strm.opaque = Z_NULL;
    strm.avail_in = 0;
    strm.next_in = Z_NULL;
    ret = inflateInit(&amp;strm);
    if (ret != Z_OK)
        return ret;
</b></pre><!-- -->
The outer <tt>do</tt>-loop decompresses input until <tt>inflate()</tt> indicates
that it has reached the end of the compressed data and has produced all of the u
output.  This is in contrast to <tt>def()</tt> which processes all of the input
If end-of-file is reached before the compressed data self-terminates, then the c
data is incomplete and an error is returned.
<pre><b>
    /* decompress until deflate stream ends or end of file */
    do {
</b></pre>
We read input data and set the <tt>strm</tt> structure accordingly.  If we've re
end of the input file, then we leave the outer loop and report an error, since t
compressed data is incomplete.  Note that we may read more data than is eventual
by <tt>inflate()</tt>, if the input file continues past the <em>zlib</em> stream
For applications where <em>zlib</em> streams are embedded in other data, this ro
need to be modified to return the unused data, or at least indicate how much of
data was not used, so the application would know where to pick up after the <em>
<pre><b>
        strm.avail_in = fread(in, 1, CHUNK, source);
        if (ferror(source)) {
            (void)inflateEnd(&amp;strm);
            return Z_ERRNO;
        }
        if (strm.avail_in == 0)
            break;
        strm.next_in = in;
</b></pre><!-- -->
The inner <tt>do</tt>-loop has the same function it did in <tt>def()</tt>, which
keep calling <tt>inflate()</tt> until has generated all of the output it can wit
provided input.
```

```
<pre><b>
        /* run inflate() on input until output buffer not full */
        do {
</b></pre>
Just like in <tt>def()</tt>, the same output space is provided for each call of
<pre><b>
            strm.avail_out = CHUNK;
            strm.next_out = out;
</b></pre>
Now we run the decompression engine itself.  There is no need to adjust the flus
the <em>zlib</em> format is self-terminating. The main difference here is that t
return values that we need to pay attention to.  <tt>Z_DATA_ERROR</tt>
indicates that <tt>inflate()</tt> detected an error in the <em>zlib</em> compres
which means that either the data is not a <em>zlib</em> stream to begin with, or
corrupted somewhere along the way since it was compressed.  The other error to b
<tt>Z_MEM_ERROR</tt>, which can occur since memory allocation is deferred until
needs it, unlike <tt>deflate()</tt>, whose memory is allocated at the start by <
<p>
Advanced applications may use
<tt>deflateSetDictionary()</tt> to prime <tt>deflate()</tt> with a set of likely
first 32K or so of compression.  This is noted in the <em>zlib</em> header, so <
requests that that dictionary be provided before it can start to decompress.  Wi
correct decompression is not possible.  For this routine, we have no idea what t
so the <tt>Z_NEED_DICT</tt> indication is converted to a <tt>Z_DATA_ERROR</tt>.
<p>
<tt>inflate()</tt> can also return <tt>Z_STREAM_ERROR</tt>, which should not be
but could be checked for as noted above for <tt>def()</tt>.  <tt>Z_BUF_ERROR</tt
checked for here, for the same reasons noted for <tt>def()</tt>.  <tt>Z_STREAM_E
checked for later.
<pre><b>
            ret = inflate(&amp;strm, Z_NO_FLUSH);
            assert(ret != Z_STREAM_ERROR);  /* state not clobbered */
            switch (ret) {
            case Z_NEED_DICT:
                ret = Z_DATA_ERROR;     /* and fall through */
            case Z_DATA_ERROR:
            case Z_MEM_ERROR:
                (void)inflateEnd(&amp;strm);
                return ret;
            }
</b></pre>
The output of <tt>inflate()</tt> is handled identically to that of <tt>deflate()
<pre><b>
            have = CHUNK - strm.avail_out;
            if (fwrite(out, 1, have, dest) != have || ferror(dest)) {
                (void)inflateEnd(&amp;strm);
                return Z_ERRNO;
            }
</b></pre>
The inner <tt>do</tt>-loop ends when <tt>inflate()</tt> has no more output as in
by not filling the output buffer, just as for <tt>deflate()</tt>.  In this case,
assert that <tt>strm.avail_in</tt> will be zero, since the deflate stream may en
does.
<pre><b>
        } while (strm.avail_out == 0);
</b></pre><!-- -->
The outer <tt>do</tt>-loop ends when <tt>inflate()</tt> reports that it has reac
end of the input <em>zlib</em> stream, has completed the decompression and integ
check, and has provided all of the output.  This is indicated by the <tt>inflate
return value <tt>Z_STREAM_END</tt>.  The inner loop is guaranteed to leave <tt>r
equal to <tt>Z_STREAM_END</tt> if the last chunk of the input file read containe
of the <em>zlib</em> stream.  So if the return value is not <tt>Z_STREAM_END</tt
loop continues to read more input.
<pre><b>
        /* done when inflate() says it's done */
    } while (ret != Z_STREAM_END);
```

```
</b></pre><!-- -->
At this point, decompression successfully completed, or we broke out of the loop
more data being available from the input file.  If the last <tt>inflate()</tt> r
is not <tt>Z_STREAM_END</tt>, then the <em>zlib</em> stream was incomplete and a
is returned.  Otherwise, we return with a happy return value.  Of course, <tt>in
is called first to avoid a memory leak.
<pre><b>
    /* clean up and return */
    (void)inflateEnd(&amp;strm);
    return ret == Z_STREAM_END ? Z_OK : Z_DATA_ERROR;
}
</b></pre><!-- -->
That ends the routines that directly use <em>zlib</em>.  The following routines
a command-line program by running data through the above routines from <tt>stdin
<tt>stdout</tt>, and handling any errors reported by <tt>def()</tt> or <tt>inf()
<p>
<tt>zerr()</tt> is used to interpret the possible error codes from <tt>def()</tt
and <tt>inf()</tt>, as detailed in their comments above, and print out an error
Note that these are only a subset of the possible return values from <tt>deflate
and <tt>inflate()</tt>.
<pre><b>
/* report a zlib or i/o error */
void zerr(int ret)
{
    fputs("zpipe: ", stderr);
    switch (ret) {
    case Z_ERRNO:
        if (ferror(stdin))
            fputs("error reading stdin\n", stderr);
        if (ferror(stdout))
            fputs("error writing stdout\n", stderr);
        break;
    case Z_STREAM_ERROR:
        fputs("invalid compression level\n", stderr);
        break;
    case Z_DATA_ERROR:
        fputs("invalid or incomplete deflate data\n", stderr);
        break;
    case Z_MEM_ERROR:
        fputs("out of memory\n", stderr);
        break;
    case Z_VERSION_ERROR:
        fputs("zlib version mismatch!\n", stderr);
    }
}
</b></pre><!-- -->

/* Illustrate the use of Z_BLOCK, inflatePrime(), and inflateSetDictionary()
   for random access of a compressed file.  A file containing a zlib or gzip
   stream is provided on the command line.  The compressed stream is decoded in
   its entirety, and an index built with access points about every SPAN bytes
   in the uncompressed output.  The compressed file is left open, and can then
   be read randomly, having to decompress on the average SPAN/2 uncompressed
   bytes before getting to the desired block of data.

   An access point can be created at the start of any deflate block, by saving
   the starting file offset and bit of that block, and the 32K bytes of
   uncompressed data that precede that block.  Also the uncompressed offset of
   that block is saved to provide a referece for locating a desired starting
   point in the uncompressed stream.  build_index() works by decompressing the
   input zlib or gzip stream a block at a time, and at the end of each block
   deciding if enough uncompressed data has gone by to justify the creation of
   a new access point.  If so, that point is saved in a data structure that
   grows as needed to accommodate the points.

   To use the index, an offset in the uncompressed data is provided, for which
   the latest accees point at or preceding that offset is located in the index.
   The input file is positioned to the specified location in the index, and if
   necessary the first few bits of the compressed data is read from the file.
   inflate is initialized with those bits and the 32K of uncompressed data, and
   the decompression then proceeds until the desired offset in the file is
   reached.  Then the decompression continues to read the desired uncompressed
   data from the file.

   Another approach would be to generate the index on demand.  In that case,
   requests for random access reads from the compressed data would try to use
   the index, but if a read far enough past the end of the index is required,
   then further index entries would be generated and added.

   There is some fair bit of overhead to starting inflation for the random
   access, mainly copying the 32K byte dictionary.  So if small pieces of the
   file are being accessed, it would make sense to implement a cache to hold
   some lookahead and avoid many calls to extract() for small lengths.

   Another way to build an index would be to use inflateCopy().  That would
   not be constrained to have access points at block boundaries, but requires
   more memory per access point, and also cannot be saved to file due to the
   use of pointers in the state.  The approach here allows for storage of the
   index in a file.

/*
   strm provides the memory allocation functions and window buffer on input,
   and provides information on the unused input on return.  For Z_DATA_ERROR
   returns, strm will also provide an error message.

   in() and out() are the call-back input and output functions.  When
   inflateBack() needs more input, it calls in().  When inflateBack() has
   filled the window with output, or when it completes with data in the
   window, it calls out() to write out the data.  The application must not
   change the provided input until in() is called again or inflateBack()
   returns.  The application must not change the window/output buffer until
   inflateBack() returns.

   in() and out() are called with a descriptor parameter provided in the
   inflateBack() call.  This parameter can be a structure that provides the
   information required to do the read or write, as well as accumulated
   information on the input and output such as totals and check values.

   in() should return zero on failure.  out() should return non-zero on
   failure.  If either in() or out() fails, than inflateBack() returns a
   Z_BUF_ERROR.  strm->next_in can be checked for Z_NULL to see whether it
   was in() or out() that caused in the error.  Otherwise,  inflateBack()
   returns Z_STREAM_END on success, Z_DATA_ERROR for an deflate format
   error, or Z_MEM_ERROR if it could not allocate memory for the state.
   inflateBack() can also return Z_STREAM_ERROR if the input parameters
   are not correct, i.e. strm is Z_NULL or the state was not initialized.

/*
   Decode literal, length, and distance codes and write out the resulting
   literal and match bytes until either not enough input or output is
   available, an end-of-block is encountered, or a data error is encountered.
   When large enough input and output buffers are supplied to inflate(), for
   example, a 16K input buffer and a 64K output buffer, more than 95% of the
   inflate execution time is spent in this routine.

   Entry assumptions:

        state->mode == LEN
        strm->avail_in >= 6
        strm->avail_out >= 258
        start >= strm->avail_out
        state->bits < 8

   On return, state->mode is one of:

        LEN -- ran out of enough output space or enough available input
        TYPE -- reached end of block code, inflate() to interpret next block
        BAD -- error in block data

   Notes:

    - The maximum input bits used by a length/distance pair is 15 bits for the
      length code, 5 bits for the length extra, 15 bits for the distance code,
      and 13 bits for the distance extra.  This totals 48 bits, or six bytes.
      Therefore if strm->avail_in >= 6, then there is enough input to avoid
      checking for available input while decoding.
```

```
    - The maximum bytes that a single length/distance pair can output is 258
      bytes, which is the maximum length that can be coded.  inflate_fast()
      requires strm->avail_out >= 258 for each loop to avoid checking for
      output space.

   inflate_fast() speedups that turned out slower (on a PowerPC G3 750CXe):
   - Using bit fields for code structure
   - Different op definition to avoid & for extra bits (do & for table bits)
   - Three separate decoding do-loops for direct, window, and wnext == 0
   - Special case for distance > 1 copies to do overlapped load and store copy
   - Explicit branch predictions (based on measured branch probabilities)
   - Deferring match copy and interspersed it with decoding subsequent codes
   - Swapping literal/length else
   - Swapping window/direct else
   - Larger unrolled copy loops (three is about right)
   - Moving len -= 3 statement into middle of loop

/*
   Decode literal, length, and distance codes and write out the resulting
   literal and match bytes until either not enough input or output is
   available, an end-of-block is encountered, or a data error is encountered.
   When large enough input and output buffers are supplied to inflate(), for
   example, a 16K input buffer and a 64K output buffer, more than 95% of the
   inflate execution time is spent in this routine.

   Entry assumptions:

        state->mode == LEN
        strm->avail_in >= 6
        strm->avail_out >= 258
        start >= strm->avail_out
        state->bits < 8

   On return, state->mode is one of:

        LEN -- ran out of enough output space or enough available input
        TYPE -- reached end of block code, inflate() to interpret next block
        BAD -- error in block data

   Notes:

    - The maximum input bits used by a length/distance pair is 15 bits for the
      length code, 5 bits for the length extra, 15 bits for the distance code,
      and 13 bits for the distance extra.  This totals 48 bits, or six bytes.
      Therefore if strm->avail_in >= 6, then there is enough input to avoid
      checking for available input while decoding.
```

```
    - The maximum bytes that a single length/distance pair can output is 258
      bytes, which is the maximum length that can be coded.  inflate_fast()
      requires strm->avail_out >= 258 for each loop to avoid checking for
      output space.

329    - Different op definition to avoid & for extra bits (do & for table bits)
330    - Three separate decoding do-loops for direct, window, and wnext == 0
331    - Special case for distance > 1 copies to do overlapped load and store copy
332    - Explicit branch predictions (based on measured branch probabilities)
333    - Deferring match copy and interspersed it with decoding subsequent codes
334    - Swapping literal/length else
335    - Swapping window/direct else
336    - Larger unrolled copy loops (three is about right)
337    - Moving len -= 3 statement into middle of loop

**********************************************************
```

```
/* inflate.c -- zlib decompression
 * Copyright (C) 1995-2012 Mark Adler
 * For conditions of distribution and use, see copyright notice in zlib.h
 */

/*
 * Change history:
 *
 * 1.2.beta0    24 Nov 2002
 * - First version -- complete rewrite of inflate to simplify code, avoid
 *   creation of window when not needed, minimize use of window when it is
 *   needed, make inffast.c even faster, implement gzip decoding, and to
 *   improve code readability and style over the previous zlib inflate code
 *
 * 1.2.beta1    25 Nov 2002
 * - Use pointers for available input and output checking in inffast.c
 * - Remove input and output counters in inffast.c
 * - Change inffast.c entry and loop from avail_in >= 7 to >= 6
 * - Remove unnecessary second byte pull from length extra in inffast.c
 * - Unroll direct copy to three copies per loop in inffast.c
 *
 * 1.2.beta2    4 Dec 2002
 * - Change external routine names to reduce potential conflicts
 * - Correct filename to inffixed.h for fixed tables in inflate.c
 * - Make hbuf[] unsigned char to match parameter type in inflate.c
 * - Change strm->next_out[-state->offset] to *(strm->next_out - state->offset)
 *   to avoid negation problem on Alphas (64 bit) in inflate.c
 *
 * 1.2.beta3    22 Dec 2002
 * - Add comments on state->bits assertion in inffast.c
 * - Add comments on op field in inftrees.h
 * - Fix bug in reuse of allocated window after inflateReset()
 * - Remove bit fields--back to byte structure for speed
 * - Remove distance extra == 0 check in inflate_fast()--only helps for lengths
 * - Change post-increments to pre-increments in inflate_fast(), PPC biased?
 * - Add compile time option, POSTINC, to use post-increments instead (Intel?)
 * - Make MATCH copy in inflate() much faster for when inflate_fast() not used
 * - Use local copies of stream next and avail values, as well as local bit
 *   buffer and bit count in inflate()--for speed when inflate_fast() not used
 *
 * 1.2.beta4    1 Jan 2003
 * - Split ptr - 257 statements in inflate_table() to avoid compiler warnings
 * - Move a comment on output buffer sizes from inffast.c to inflate.c
 * - Add comments in inffast.c to introduce the inflate_fast() routine
 * - Rearrange window copies in inflate_fast() for speed and simplification
 * - Unroll last copy for window match in inflate_fast()
 * - Use local copies of window variables in inflate_fast() for speed
 * - Pull out common wnext == 0 case for speed in inflate_fast()
 * - Make op and len in inflate_fast() unsigned for consistency
 * - Add FAR to lcode and dcode declarations in inflate_fast()
 * - Simplified bad distance check in inflate_fast()
 * - Added inflateBackInit(), inflateBack(), and inflateBackEnd() in new
 *   source file infback.c to provide a call-back interface to inflate for
 *   programs like gzip and unzip -- uses window as output buffer to avoid
 *   window copying
 *
 * 1.2.beta5    1 Jan 2003
 * - Improved inflateBack() interface to allow the caller to provide initial
 *   input in strm.
 * - Fixed stored blocks bug in inflateBack()
```

```
 *
 * 1.2.beta6    4 Jan 2003
 * - Added comments in inffast.c on effectiveness of POSTINC
 * - Typecasting all around to reduce compiler warnings
 * - Changed loops from while (1) or do {} while (1) to for (;;), again to
 *   make compilers happy
 * - Changed type of window in inflateBackInit() to unsigned char *
 *
 * 1.2.beta7    27 Jan 2003
 * - Changed many types to unsigned or unsigned short to avoid warnings
 * - Added inflateCopy() function
 *
 * 1.2.0        9 Mar 2003
 * - Changed inflateBack() interface to provide separate opaque descriptors
 *   for the in() and out() functions
 * - Changed inflateBack() argument and in_func typedef to swap the length
 *   and buffer address return values for the input function
 * - Check next_in and next_out for Z_NULL on entry to inflate()
 *
 * The history for versions after 1.2.0 are in ChangeLog in zlib distribution.

/*
   Update the window with the last wsize (normally 32K) bytes written before
   returning.  If window does not exist yet, create it.  This is only called
   when a window is already in use, or when output has been written during this
   inflate call, but the end of the deflate stream has not been reached yet.
   It is also called to create a window for dictionary data when a dictionary
   is loaded.

   Providing output buffers larger than 32K to inflate() should provide a speed
   advantage, since only the last 32K of output is copied to the sliding window
   upon return from inflate(), and since all distances after the first 32K of
   output will fall in the output data, making match copies simpler and faster.
   The advantage may be dependent on the size of the processor's data caches.

```

```
/*
   inflate() uses a state machine to process as much input data and generate as
   much output data as possible before returning.  The state machine is
   structured roughly as follows:

    for (;;) switch (state) {
    ...
    case STATEn:
        if (not enough input data or output space to make progress)
            return;
        ... make progress ...
        state = STATEm;
        break;
    ...
    }

   so when inflate() is called again, the same case is attempted again, and
   if the appropriate resources are provided, the machine proceeds to the
   next state.  The NEEDBITS() macro is usually the way the state evaluates
   whether it can proceed or should return.  NEEDBITS() does the return if
   the requested bits are not available.  The typical use of the BITS macros
   is:

        NEEDBITS(n);
        ... do something with BITS(n) ...
        DROPBITS(n);

   where NEEDBITS(n) either returns from inflate() if there isn't enough
   input left to load n bits into the accumulator, or it continues.  BITS(n)
   gives the low n bits in the accumulator.  When done, DROPBITS(n) drops
   the low n bits off the accumulator.  INITBITS() clears the accumulator
   and sets the number of available bits to zero.  BYTEBITS() discards just
   enough bits to put the accumulator on a byte boundary.  After BYTEBITS()
   and a NEEDBITS(8), then BITS(8) would return the next byte in the stream.

   NEEDBITS(n) uses PULLBYTE() to get an available byte of input, or to return
   if there is no input available.  The decoding of variable length codes uses
   PULLBYTE() directly in order to pull just enough bytes to decode the next
   code, and no more.

   Some states loop until they get enough input, making sure that enough
   state information is maintained to continue the loop where it left off
   if NEEDBITS() returns in the loop.  For example, want, need, and keep
   would all have to actually be part of the saved state in case NEEDBITS()
   returns:

    case STATEw:
        while (want < need) {
            NEEDBITS(n);
            keep[want++] = BITS(n);
            DROPBITS(n);
        }
        state = STATEx;
    case STATEx:

   As shown above, if the next state is also the next case, then the break
   is omitted.

   A state may also return if there is not enough output space available to
   complete that state.  Those states are copying stored data, writing a
   literal byte, and copying a matching string.

   When returning, a "goto inf_leave" is used to update the total counters,
   update the check value, and determine whether any progress has been made
   during that inflate() call in order to return the proper return code.
   Progress is defined as a change in either strm->avail_in or strm->avail_out.
```

```
   When there is a window, goto inf_leave will update the window with the last
   output written.  If a goto inf_leave occurs in the middle of decompression
   and there is no window currently, goto inf_leave will create one and copy
   output to the window for the next call of inflate().

   In this implementation, the flush parameter of inflate() only affects the
   return code (per zlib.h).  inflate() always writes as much as possible to
   strm->next_out, given the space available and the provided input--the effect
   documented in zlib.h of Z_SYNC_FLUSH.  Furthermore, inflate() always defers
   the allocation of and copying into a sliding window until necessary, which
   provides the effect documented in zlib.h for Z_FINISH when the entire input
   stream available.  So the only thing the flush parameter actually does is:
   when flush is set to Z_FINISH, inflate() cannot return Z_OK.  Instead it
   will return Z_BUF_ERROR if it has not reached the end of the stream.

    /*
       Process a set of code lengths to create a canonical Huffman code.  The
       code lengths are lens[0..codes-1].  Each length corresponds to the
       symbols 0..codes-1.  The Huffman code is generated by first sorting the
       symbols by length from short to long, and retaining the symbol order
       for codes with equal lengths.  Then the code starts with all zero bits
       for the first code of the shortest length, and the codes are integer
       increments for the same length, and zeros are appended as the length
       increases.  For the deflate format, these bits are stored backwards
       from their more natural integer increment ordering, and so when the
       decoding tables are built in the large loop below, the integer codes
       are incremented backwards.

       This routine assumes, but does not check, that all of the entries in
       lens[] are in the range 0..MAXBITS.  The caller must assure this.
       1..MAXBITS is interpreted as that code length.  zero means that that
       symbol does not occur in this code.

       The codes are sorted by computing a count of codes for each length,
       creating from that a table of starting indices for each length in the
       sorted table, and then entering the symbols in order in the sorted
       table.  The sorted table is work[], with that space being provided by
       the caller.

       The length counts are used for other purposes as well, i.e. finding
       the minimum and maximum length codes, determining if there are any
       codes at all, checking for a valid set of lengths, and looking ahead
       at length counts to determine sub-table sizes when building the
       decoding tables.
     */

    offs[1] = 0;
    for (len = 1; len < MAXBITS; len++)
        offs[len + 1] = offs[len] + count[len];

    /* sort symbols by length, by symbol order within each length */
    for (sym = 0; sym < codes; sym++)
        if (lens[sym] != 0) work[offs[lens[sym]]++] = (unsigned short)sym;

    /*
       Create and fill in decoding tables.  In this loop, the table being
       filled is at next and has curr index bits.  The code being used is huff
       with length len.  That code is converted to an index by dropping drop
       bits off of the bottom.  For codes where len is less than drop + curr,
       those top drop + curr - len bits are incremented through all values to
       fill the table with replicated entries.

       root is the number of index bits for the root table.  When len exceeds
       root, sub-tables are created pointed to by the root entry with an index
       of the low root bits of huff.  This is saved in low to check for when a
       new sub-table should be started.  drop is zero when the root table is
       being filled, and drop is root when sub-tables are being filled.

       When a new sub-table is needed, it is necessary to look ahead in the
       code lengths to determine what size sub-table is needed.  The length
       counts are used for this, and so count[] is decremented as codes are
       entered in the tables.

       used keeps track of how many table entries have been allocated from the
       provided *table space.  It is checked for LENS and DIST tables against
       the constants ENOUGH_LENS and ENOUGH_DISTS to guard against changes in
       the initial root table size constants.  See the comments in inftrees.h
       for more information.

       sym increments through all symbols, and the loop terminates when
       all codes of length max, i.e. all codes, have been processed.  This
       routine permits incomplete codes, so another loop after this one fills
       in the rest of the decoding tables with invalid code markers.

/* Structure for decoding tables.  Each entry provides either the
   information needed to do the operation requested by the code that
   indexed that table entry, or it provides a pointer to another
   table that indexes more bits of the code.  op indicates whether
   the entry is a pointer to another table, a literal, a length or
   distance, an end-of-block, or an invalid code.  For a table
   pointer, the low four bits of op is the number of index bits of
   that table.  For a length or distance, the low four bits of op
   is the number of extra bits to get after the code.  bits is
   the number of bits in this code or part of the code to drop off
   of the bit buffer.  val is the actual byte to output in the case
   of a literal, the base length or distance, or the offset from
   the current table to the next table.  Each entry is four bytes. */

# Makefile for zlib
# Borland C++
# Last updated: 15-Mar-2003

# To use, do "make -fmakefile.bor"
# To compile in small model, set below: MODEL=s

# WARNING: the small model is supported but only for small values of
# MAX_WBITS and MAX_MEM_LEVEL. For example:
#    -DMAX_WBITS=11 -DDEF_WBITS=11 -DMAX_MEM_LEVEL=3
# If you wish to reduce the memory requirements (default 256K for big
# objects plus a few K), you can add to the LOC macro below:
#   -DMAX_MEM_LEVEL=7 -DMAX_WBITS=14
# See zconf.h for details about the memory requirements.

# ------------ Turbo C++, Borland C++ ------------

#    Optional nonstandard preprocessor flags (e.g. -DMAX_MEM_LEVEL=7)
#    should be added to the environment via "set LOCAL_ZLIB=-DFOO" or added
#    to the declaration of LOC here:
LOC = $(LOCAL_ZLIB)

# type for CPU required: 0: 8086, 1: 80186, 2: 80286, 3: 80386, etc.
CPU_TYP = 0

# memory model: one of s, m, c, l (small, medium, compact, large)
MODEL=l

# replace bcc with tcc for Turbo C++ 1.0, with bcc32 for the 32 bit version
CC=bcc
LD=bcc
AR=tlib

  1 # Makefile for zlib.  Modified for djgpp v2.0 by F. J. Donahoe, 3/15/96.
  2 # Copyright (C) 1995-1998 Jean-loup Gailly.
  3 # For conditions of distribution and use, see copyright notice in zlib.h

  5 # To compile, or to compile and test, type:
  6 #
  7 #   make -fmakefile.dj2;  make test -fmakefile.dj2
  8 #
  9 # To install libz.a, zconf.h and zlib.h in the djgpp directories, type:
 10 #
 11 #    make install -fmakefile.dj2
 12 #
 13 # after first defining LIBRARY_PATH and INCLUDE_PATH in djgpp.env as
 14 # in the sample below if the pattern of the DJGPP distribution is to
 15 # be followed.  Remember that, while <sp>'es around <=> are ignored in
 16 # makefiles, they are *not* in batch files or in djgpp.env.
 17 # - - - - -
 18 # [make]
 19 # INCLUDE_PATH=%\>;INCLUDE_PATH%%\DJDIR%\include
 20 # LIBRARY_PATH=%\>;LIBRARY_PATH%%\DJDIR%\lib
 21 # BUTT=-m486
 22 # - - - - -
 23 # Alternately, these variables may be defined below, overriding the values
 24 # in djgpp.env, as
 25 # INCLUDE_PATH=c:\usr\include
 26 # LIBRARY_PATH=c:\usr\lib

# Makefile for zlib
# Microsoft C 5.1 or later
# Last updated: 19-Mar-2003

# To use, do "make makefile.msc"
# To compile in small model, set below: MODEL=S

# If you wish to reduce the memory requirements (default 256K for big
# objects plus a few K), you can add to the LOC macro below:
#   -DMAX_MEM_LEVEL=7 -DMAX_WBITS=14
# See zconf.h for details about the memory requirements.

# ------------- Microsoft C 5.1 and later -------------

#    Optional nonstandard preprocessor flags (e.g. -DMAX_MEM_LEVEL=7)
#    should be added to the environment via "set LOCAL_ZLIB=-DFOO" or added
#    to the declaration of LOC here:
LOC = $(LOCAL_ZLIB)

# Type for CPU required: 0: 8086, 1: 80186, 2: 80286, 3: 80386, etc.
CPU_TYP = 0

# Memory model: one of S, M, C, L (small, medium, compact, large)
MODEL=L

CC=cl
CFLAGS=-nologo -A$(MODEL) -G$(CPU_TYP) -W3 -Oait -Gs $(LOC)
#-Ox generates bad code with MSC 5.1
LIB_CFLAGS=-Zl $(CFLAGS)

LD=link
LDFLAGS=/noi/e/st:0x1500/noe/farcall/packcode
# "/farcall/packcode" are only useful for ‘large code’ memory models
# but should be a "no-op" for small code models.

```

```
See below some functions declarations for Visual Basic.

Frequently Asked Question:

Q: Each time I use the compress function I get the -5 error (not enough
   room in the output buffer).

A: Make sure that the length of the compressed buffer is passed by
   reference ("as any"), not by value ("as long"). Also check that
   before the call of compress this length is equal to the total size of
   the compressed buffer and not zero.

From: "Jon Caruana" <jon-net@usa.net>
Subject: Re: How to port zlib declares to vb?
Date: Mon, 28 Oct 1996 18:33:03 -0600

Got the answer! (I haven't had time to check this but it's what I got, and
looks correct):

He has the following routines working:
        compress
        uncompress
        gzopen
        gzwrite
        gzread
        gzclose

Declares follow: (Quoted from Carlos Rios <c_rios@sonda.cl>, in Vb4 form)

#If Win16 Then   'Use Win16 calls.
Declare Function compress Lib "ZLIB.DLL" (ByVal compr As
        String, comprLen As Any, ByVal buf As String, ByVal buflen
        As Long) As Integer
Declare Function uncompress Lib "ZLIB.DLL" (ByVal uncompr
        As String, uncomprLen As Any, ByVal compr As String, ByVal
        lcompr As Long) As Integer
Declare Function gzopen Lib "ZLIB.DLL" (ByVal filePath As
        String, ByVal mode As String) As Long
Declare Function gzread Lib "ZLIB.DLL" (ByVal file As
        Long, ByVal uncompr As String, ByVal uncomprLen As Integer)
        As Integer
Declare Function gzwrite Lib "ZLIB.DLL" (ByVal file As
        Long, ByVal uncompr As String, ByVal uncomprLen As Integer)
        As Integer
Declare Function gzclose Lib "ZLIB.DLL" (ByVal file As
        Long) As Integer
#Else
Declare Function compress Lib "ZLIB32.DLL"
        (ByVal compr As String, comprLen As Any, ByVal buf As
        String, ByVal buflen As Long) As Integer
Declare Function uncompress Lib "ZLIB32.DLL"
        (ByVal uncompr As String, uncomprLen As Any, ByVal compr As
        String, ByVal lcompr As Long) As Long
Declare Function gzopen Lib "ZLIB32.DLL"
        (ByVal file As String, ByVal mode As String) As Long
Declare Function gzread Lib "ZLIB32.DLL"
        (ByVal file As Long, ByVal uncompr As String, ByVal
        uncomprLen As Long) As Long
Declare Function gzwrite Lib "ZLIB32.DLL"
```

```
        (ByVal file As Long, ByVal uncompr As String, ByVal
        uncomprLen As Long) As Long
Declare Function gzclose Lib "ZLIB32.DLL"
        (ByVal file As Long) As Long
#End If

Here is another example from Michael <michael_borgsys@hotmail.com> that he
says conforms to the VB guidelines, and that solves the problem of not
knowing the uncompressed size by storing it at the end of the file:

'Calling the functions:
'bracket meaning: <parameter> [optional] {Range of possible values}
'Call subCompressFile(<path with filename to compress> [, <path with
filename to write to>, [level of compression {1..9}]])
'Call subUncompressFile(<path with filename to compress>)

Option Explicit
Private lngpvtPcnSml As Long 'Stores value for 'lngPercentSmaller'
Private Const SUCCESS As Long = 0
Private Const strFilExt As String = ".cpr"
Private Declare Function lngfncCpr Lib "zlib.dll" Alias "compress2" (ByRef
dest As Any, ByRef destLen As Any, ByRef src As Any, ByVal srcLen As Long,
ByVal level As Integer) As Long
Private Declare Function lngfncUcp Lib "zlib.dll" Alias "uncompress" (ByRef
dest As Any, ByRef destLen As Any, ByRef src As Any, ByVal srcLen As Long)
As Long

Public Sub subCompressFile(ByVal strargOriFilPth As String, Optional ByVal
strargCprFilPth As String, Optional ByVal intLvl As Integer = 9)
    Dim strCprPth As String
    Dim lngOriSiz As Long
    Dim lngCprSiz As Long

/* -- memory tracking routines -- */

/*
   These memory tracking routines are provided to zlib and track all of zlib's
   allocations and deallocations, check for LIFO operations, keep a current
   and high water mark of total bytes requested, optionally set a limit on the
   total memory that can be allocated, and when done check for memory leaks.

   They are used as follows:

   z_stream strm;
   mem_setup(&strm)         initializes the memory tracking and sets the
                            zalloc, zfree, and opaque members of strm to use
                            memory tracking for all zlib operations on strm
   mem_limit(&strm, limit)  sets a limit on the total bytes requested -- a
                            request that exceeds this limit will result in an
                            allocation failure (returns NULL) -- setting the
                            limit to zero means no limit, which is the default
                            after mem_setup()
   mem_used(&strm, "msg")   prints to stderr "msg" and the total bytes used
   mem_high(&strm, "msg")   prints to stderr "msg" and the high water mark
   mem_done(&strm, "msg")   ends memory tracking, releases all allocations
                            for the tracking as well as leaked zlib blocks, if
                            any.  If there was anything unusual, such as leaked
                            blocks, non-FIFO frees, or frees of addresses not
                            allocated, then "msg" and information about the
                            problem is printed to stderr.  If everything is
                            normal, nothing is printed. mem_done resets the
                            strm members to Z_NULL to use the default memory
                            allocation routines on the next zlib initialization
                            using strm.

 * For conditions of distribution and use, see copyright notice in zlib.h
 */

/*
 *  ALGORITHM
 *
 *      The "deflation" process uses several Huffman trees. The more
 *      common source values are represented by shorter bit sequences.
 *
 *      Each code tree is stored in a compressed form which is itself
 * a Huffman encoding of the lengths of all the code strings (in
 * ascending order by source values).  The actual code strings are
 * reconstructed from the lengths in the inflate process, as described
 * in the deflate specification.

#include "zlib.h"

/* ===========================================================================
     Decompresses the source buffer into the destination buffer.  sourceLen is
   the byte length of the source buffer. Upon entry, destLen is the total
   size of the destination buffer, which must be large enough to hold the
   entire uncompressed data. (The size of the uncompressed data must have
   been saved previously by the compressor and transmitted to the decompressor
   by some mechanism outside the scope of this compression library.)
   Upon exit, destLen is the actual size of the compressed buffer.

     uncompress returns Z_OK if success, Z_MEM_ERROR if there was not
   enough memory, Z_BUF_ERROR if there was not enough room in the output
   buffer, or Z_DATA_ERROR if the input data was corrupted.

  2             Frequently Asked Questions about ZLIB1.DLL

  5 This document describes the design, the rationale, and the usage
  6 of the official DLL build of zlib, named ZLIB1.DLL.  If you have
  7 general questions about zlib, you should see the file "FAQ" found
  8 in the zlib distribution, or at the following location:
  9   http://www.gzip.org/zlib/zlib_faq.html

 12  1. What is ZLIB1.DLL, and how can I get it?

 14   - ZLIB1.DLL is the official build of zlib as a DLL.
 15     (Please remark the character '1' in the name.)

 17     Pointers to a precompiled ZLIB1.DLL can be found in the zlib
 18     web site at:
 19       http://www.zlib.net/

 21     Applications that link to ZLIB1.DLL can rely on the following
 22     specification:

 24     * The exported symbols are exclusively defined in the source
 25       files "zlib.h" and "zlib.def", found in an official zlib
 26       source distribution.
 27     * The symbols are exported by name, not by ordinal.
 28     * The exported names are undecorated.
 29     * The calling convention of functions is "C" (CDECL).
 30     * The ZLIB1.DLL binary is linked to MSVCRT.DLL.

 32     The archive in which ZLIB1.DLL is bundled contains compiled
 33     test programs that must run with a valid build of ZLIB1.DLL.
 34     It is recommended to download the prebuilt DLL from the zlib
 35     web site, instead of building it yourself, to avoid potential
 36     incompatibilities that could be introduced by your compiler
 37     and build settings.  If you do build the DLL yourself, please
 38     make sure that it complies with all the above requirements,
 39     and it runs with the precompiled test programs, bundled with
 40     the original ZLIB1.DLL distribution.

 42     If, for any reason, you need to build an incompatible DLL,
 43     please use a different file name.

 46  2. Why did you change the name of the DLL to ZLIB1.DLL?
 47     What happened to the old ZLIB.DLL?

 49   - The old ZLIB.DLL, built from zlib-1.1.4 or earlier, required
 50     compilation settings that were incompatible to those used by
 51     a static build.  The DLL settings were supposed to be enabled
 52     by defining the macro ZLIB_DLL, before including "zlib.h".
 53     Incorrect handling of this macro was silently accepted at
 54     build time, resulting in two major problems:

 56     * ZLIB_DLL was missing from the old makefile.  When building
 57       the DLL, not all people added it to the build options.  In
 58       consequence, incompatible incarnations of ZLIB.DLL started
 59       to circulate around the net.
```

```
 61     * When switching from using the static library to using the
 62       DLL, applications had to define the ZLIB_DLL macro and
 63       to recompile all the sources that contained calls to zlib
 64       functions.  Failure to do so resulted in creating binaries
 65       that were unable to run with the official ZLIB.DLL build.

 67     The only possible solution that we could foresee was to make
 68     a binary-incompatible change in the DLL interface, in order to
 69     remove the dependency on the ZLIB_DLL macro, and to release
 70     the new DLL under a different name.

 72     We chose the name ZLIB1.DLL, where '1' indicates the major
 73     zlib version number.  We hope that we will not have to break
 74     the binary compatibility again, at least not as long as the
 75     zlib-1.x series will last.

 77     There is still a ZLIB_DLL macro, that can trigger a more
 78     efficient build and use of the DLL, but compatibility no
 79     longer dependents on it.

 82  3. Can I build ZLIB.DLL from the new zlib sources, and replace
 83     an old ZLIB.DLL, that was built from zlib-1.1.4 or earlier?

 85   - In principle, you can do it by assigning calling convention
 86     keywords to the macros ZEXPORT and ZEXPORTVA.  In practice,
 87     it depends on what you mean by "an old ZLIB.DLL", because the
 88     old DLL exists in several mutually-incompatible versions.
 89     You have to find out first what kind of calling convention is
 90     being used in your particular ZLIB.DLL build, and to use the
 91     same one in the new build.  If you don't know what this is all
 92     about, you might be better off if you would just leave the old
 93     DLL intact.

 96  4. Can I compile my application using the new zlib interface, and
 97     link it to an old ZLIB.DLL, that was built from zlib-1.1.4 or
 98     earlier?

100   - The official answer is "no"; the real answer depends again on
101     what kind of ZLIB.DLL you have.  Even if you are lucky, this
102     course of action is unreliable.

104     If you rebuild your application and you intend to use a newer
105     version of zlib (post- 1.1.4), it is strongly recommended to
106     link it to the new ZLIB1.DLL.

109  5. Why are the zlib symbols exported by name, and not by ordinal?

111   - Although exporting symbols by ordinal is a little faster, it
112     is risky.  Any single glitch in the maintenance or use of the
113     DEF file that contains the ordinals can result in incompatible
114     builds and frustrating crashes.  Simply put, the benefits of
115     exporting symbols by ordinal do not justify the risks.

117     Technically, it should be possible to maintain ordinals in
118     the DEF file, and still export the symbols by name.  Ordinals
119     exist in every DLL, and even if the dynamic linking performed
120     at the DLL startup is searching for names, ordinals serve as
121     hints, for a faster name lookup.  However, if the DEF file
122     contains ordinals, the Microsoft linker automatically builds
123     an implib that will cause the executables linked to it to use
124     those ordinals, and not the names.  It is interesting to
125     notice that the GNU linker for Win32 does not suffer from this
126     problem.
```

It is possible to avoid the DEF file if the exported symbols are accompanied by a "__declspec(dllexport)" attribute in the source files. You can do this in zlib by predefining the ZLIB_DLL macro.

6. I see that the ZLIB1.DLL functions use the "C" (CDECL) calling convention. Why not use the STDCALL convention? STDCALL is the standard convention in Win32, and I need it in my Visual Basic project!

(For readability, we use CDECL to refer to the convention triggered by the "__cdecl" keyword, STDCALL to refer to the convention triggered by "__stdcall", and FASTCALL to refer to the convention triggered by "__fastcall".)

- Most of the native Windows API functions (without varargs) use indeed the WINAPI convention (which translates to STDCALL in Win32), but the standard C functions use CDECL. If a user application is intrinsically tied to the Windows API (e.g. it calls native Windows API functions such as CreateFile()), sometimes it makes sense to decorate its own functions with WINAPI. But if ANSI C or POSIX portability is a goal (e.g. it calls standard C functions such as fopen()), it is not a sound decision to request the inclusion of <windows.h>, or to use non-ANSI constructs, for the sole purpose to make the user functions STDCALL-able.

  The functionality offered by zlib is not in the category of "Windows functionality", but is more like "C functionality".

  Technically, STDCALL is not bad; in fact, it is slightly faster than CDECL, and it works with variable-argument functions, just like CDECL. It is unfortunate that, in spite of using STDCALL in the Windows API, it is not the default convention used by the C compilers that run under Windows. The roots of the problem reside deep inside the unsafety of the K&R-style function prototypes, where the argument types are not specified; but that is another story for another day.

  The remaining fact is that CDECL is the default convention. Even if an explicit convention is hard-coded into the function prototypes inside C headers, problems may appear. The necessity to expose the convention in users' callbacks is one of these problems.

  The calling convention issues are also important when using zlib in other programming languages. Some of them, like Ada (GNAT) and Fortran (GNU G77), have C bindings implemented initially on Unix, and relying on the C calling convention. On the other hand, the pre- .NET versions of Microsoft Visual Basic require STDCALL, while Borland Delphi prefers, although it does not require, FASTCALL.

  In fairness to all possible uses of zlib outside the C programming language, we choose the default "C" convention. Anyone interested in different bindings or conventions is encouraged to maintain specialized projects. The "contrib/" directory from the zlib distribution already holds a couple of foreign bindings, such as Ada, C++, and Delphi.

7. I need a DLL for my Visual Basic project. What can I do?

- Define the ZLIB_WINAPI macro before including "zlib.h", when

building both the DLL and the user application (except that you don't need to define anything when using the DLL in Visual Basic). The ZLIB_WINAPI macro will switch on the WINAPI (STDCALL) convention. The name of this DLL must be different than the official ZLIB1.DLL.

Gilles Vollant has contributed a build named ZLIBWAPI.DLL, with the ZLIB_WINAPI macro turned on, and with the minizip functionality built in. For more information, please read the notes inside "contrib/vstudio/readme.txt", found in the zlib distribution.

8. I need to use zlib in my Microsoft .NET project. What can I do?

- Henrik Ravn has contributed a .NET wrapper around zlib. Look into contrib/dotzlib/, inside the zlib distribution.

9. If my application uses ZLIB1.DLL, should I link it to MSVCRT.DLL? Why?

- It is not required, but it is recommended to link your application to MSVCRT.DLL, if it uses ZLIB1.DLL.

  The executables (.EXE, .DLL, etc.) that are involved in the same process and are using the C run-time library (i.e. they are calling standard C functions), must link to the same library. There are several libraries in the Win32 system: CRTDLL.DLL, MSVCRT.DLL, the static C libraries, etc. Since ZLIB1.DLL is linked to MSVCRT.DLL, the executables that depend on it should also be linked to MSVCRT.DLL.

10. Why are you saying that ZLIB1.DLL and my application should be linked to the same C run-time (CRT) library? I linked my application and my DLLs to different C libraries (e.g. my application to a static library, and my DLLs to MSVCRT.DLL), and everything works fine.

- If a user library invokes only pure Win32 API (accessible via <windows.h> and the related headers), its DLL build will work in any context. But if this library invokes standard C API, things get more complicated.

  There is a single Win32 library in a Win32 system. Every function in this library resides in a single DLL module, that is safe to call from anywhere. On the other hand, there are multiple versions of the C library, and each of them has its own separate internal state. Standalone executables and user DLLs that call standard C functions must link to a C run-time (CRT) library, be it static or shared (DLL). Intermixing occurs when an executable (not necessarily standalone) and a DLL are linked to different CRTs, and both are running in the same process.

  Intermixing multiple CRTs is possible, as long as their internal states are kept intact. The Microsoft Knowledge Base articles KB94248 "HOWTO: Use the C Run-Time" and KB140584 "HOWTO: Link with the Correct C Run-Time (CRT) Library" mention the potential problems raised by intermixing.

  If intermixing works for you, it's because your application and DLLs are avoiding the corruption of each of the CRTs' internal states, maybe by careful design, or maybe by fortune.

Also note that linking ZLIB1.DLL to non-Microsoft CRTs, such as those provided by Borland, raises similar problems.

11. Why are you linking ZLIB1.DLL to MSVCRT.DLL?

- MSVCRT.DLL exists on every Windows 95 with a new service pack installed, or with Microsoft Internet Explorer 4 or later, and on all other Windows 4.x or later (Windows 98, Windows NT 4, or later). It is freely distributable; if not present in the system, it can be downloaded from Microsoft or from other software provider for free.

  The fact that MSVCRT.DLL does not exist on a virgin Windows 95 is not so problematic. Windows 95 is scarcely found nowadays, Microsoft ended its support a long time ago, and many recent applications from various vendors, including Microsoft, do not even run on it. Furthermore, no serious user should run Windows 95 without a proper update installed.

12. Why are you not linking ZLIB1.DLL to <<my favorite C run-time library>> ?

- We considered and abandoned the following alternatives:

  * Linking ZLIB1.DLL to a static C library (LIBC.LIB, or LIBCMT.LIB) is not a good option. People are using the DLL mainly to save disk space. If you are linking your program to a static C library, you may as well consider linking zlib in statically, too.

  * Linking ZLIB1.DLL to CRTDLL.DLL looks appealing, because CRTDLL.DLL is present on every Win32 installation. Unfortunately, it has a series of problems: it does not work properly with Microsoft's C++ libraries, it does not provide support for 64-bit file offsets, (and so on...), and Microsoft discontinued its support a long time ago.

  * Linking ZLIB1.DLL to MSVCR70.DLL or MSVCR71.DLL, supplied with the Microsoft .NET platform, and Visual C++ 7.0/7.1, raises problems related to the status of ZLIB1.DLL as a system component. According to the Microsoft Knowledge Base article KB326922 "INFO: Redistribution of the Shared C Runtime Component in Visual C++ .NET", MSVCR70.DLL and MSVCR71.DLL are not supposed to function as system DLLs, because they may clash with MSVCRT.DLL. Instead, the application's installer is supposed to put these DLLs (if needed) in the application's private directory. If ZLIB1.DLL depends on a non-system runtime, it cannot function as a redistributable system component.

  * Linking ZLIB1.DLL to non-Microsoft runtimes, such as Borland's, or Cygwin's, raises problems related to the reliable presence of these runtimes on Win32 systems. It's easier to let the DLL build of zlib up to the people who distribute these runtimes, and who may proceed as explained in the answer to Question 14.

13. If ZLIB1.DLL cannot be linked to MSVCR70.DLL or MSVCR71.DLL, how can I build/use ZLIB1.DLL in Microsoft Visual C++ 7.0 (Visual Studio .NET) or newer?

- Due to the problems explained in the Microsoft Knowledge Base

article KB326922 (see the previous answer), the C runtime that comes with the VC7 environment is no longer considered a system component. That is, it should not be assumed that this runtime exists, or may be installed in a system directory. Since ZLIB1.DLL is supposed to be a system component, it may not depend on a non-system component.

In order to link ZLIB1.DLL and your application to MSVCRT.DLL in VC7, you need the library of Visual C++ 6.0 or older. If you don't have this library at hand, it's probably best not to use ZLIB1.DLL.

We are hoping that, in the future, Microsoft will provide a way to build applications linked to a proper system runtime, from the Visual C++ environment. Until then, you have a couple of alternatives, such as linking zlib in statically. If your application requires dynamic linking, you may proceed as explained in the answer to Question 14.

14. I need to link my own DLL build to a CRT different than MSVCRT.DLL. What can I do?

- Feel free to rebuild the DLL from the zlib sources, and link it the way you want. You should, however, clearly state that your build is unofficial. You should give it a different file name, and/or install it in a private directory that can be accessed by your application only, and is not visible to the others (i.e. it's neither in the PATH, nor in the SYSTEM or SYSTEM32 directories). Otherwise, your build may clash with applications that link to the official build.

  For example, in Cygwin, zlib is linked to the Cygwin runtime CYGWIN1.DLL, and it is distributed under the name CYGZ.DLL.

15. May I include additional pieces of code that I find useful, link them in ZLIB1.DLL, and export them?

- No. A legitimate build of ZLIB1.DLL must not include code that does not originate from the official zlib source code. But you can make your own private DLL build, under a different file name, as suggested in the previous answer.

  For example, zlib is a part of the VCL library, distributed with Borland Delphi and C++ Builder. The DLL build of VCL is a redistributable file, named VCLxx.DLL.

16. May I remove some functionality out of ZLIB1.DLL, by enabling macros like NO_GZCOMPRESS or NO_GZIP at compile time?

- No. A legitimate build of ZLIB1.DLL must provide the complete zlib functionality, as implemented in the official zlib source code. But you can make your own private DLL build, under a different file name, as suggested in the previous answer.

17. I made my own ZLIB1.DLL build. Can I test it for compliance?

- We prefer that you download the official DLL from the zlib web site. If you need something peculiar from this DLL, you can send your suggestion to the zlib mailing list.

  However, in case you do rebuild the DLL yourself, you can run it with the test programs found in the DLL distribution.

```
391     Running these test programs is not a guarantee of compliance,
392     but a failure can imply a detected problem.

ZLIB DATA COMPRESSION LIBRARY

zlib 1.2.8 is a general purpose data compression library.  All the code is
thread safe.  The data format used by the zlib library is described by RFCs
(Request for Comments) 1950 to 1952 in the files
http://www.ietf.org/rfc/rfc1950.txt (zlib format), rfc1951.txt (deflate format)
and rfc1952.txt (gzip format).

All functions of the compression library are documented in the file zlib.h
(volunteer to write man pages welcome, contact zlib@gzip.org).  Two compiled
examples are distributed in this package, example and minigzip.  The example_d
and minigzip_d flavors validate that the zlib1.dll file is working correctly.

Questions about zlib should be sent to <zlib@gzip.org>.  The zlib home page
is http://zlib.net/ .  Before reporting a problem, please check this site to
verify that you have the latest version of zlib; otherwise get the latest
version and check whether the problem still exists or not.

PLEASE read DLL_FAQ.txt, and the the zlib FAQ http://zlib.net/zlib_faq.html
before asking for help.

Manifest:

The package zlib-1.2.8-win32-x86.zip will contain the following files:

  README-WIN32.txt This document
  ChangeLog        Changes since previous zlib packages
  DLL_FAQ.txt      Frequently asked questions about zlib1.dll
  zlib.3.pdf       Documentation of this library in Adobe Acrobat format

  example.exe      A statically-bound example (using zlib.lib, not the dll)
  example.pdb      Symbolic information for debugging example.exe

  example_d.exe    A zlib1.dll bound example (using zdll.lib)
  example_d.pdb    Symbolic information for debugging example_d.exe

  minigzip.exe     A statically-bound test program (using zlib.lib, not the dll)
  minigzip.pdb     Symbolic information for debugging minigzip.exe

  minigzip_d.exe   A zlib1.dll bound test program (using zdll.lib)
  minigzip_d.pdb   Symbolic information for debugging minigzip_d.exe

  zlib.h           Install these files into the compilers' INCLUDE path to
  zconf.h          compile programs which use zlib.lib or zdll.lib

  zdll.lib         Install these files into the compilers' LIB path if linking
  zdll.exp         a compiled program to the zlib1.dll binary

  zlib.lib         Install these files into the compilers' LIB path to link zlib
  zlib.pdb         into compiled programs, without zlib1.dll runtime dependency
                   (zlib.pdb provides debugging info to the compile time linker)

  zlib1.dll        Install this binary shared library into the system PATH, or
                   the program's runtime directory (where the .exe resides)
  zlib1.pdb        Install in the same directory as zlib1.dll, in order to debug
                   an application crash using WinDbg or similar tools.

All .pdb files above are entirely optional, but are very useful to a developer
attempting to diagnose program misbehavior or a crash.  Many additional
```

```
important files for developers can be found in the zlib127.zip source package
available from http://zlib.net/ - review that package's README file for details.

Acknowledgments:

The deflate format used by zlib was defined by Phil Katz.  The deflate and
zlib specifications were written by L.  Peter Deutsch.  Thanks to all the
people who reported problems and suggested various improvements in zlib; they
are too numerous to cite here.

            (1 << (windowBits+2)) +  (1 << (memLevel+9))
 that is: 128K for windowBits=15  +  128K for memLevel = 8  (default values)
 plus a few kilobytes for small objects. For example, if you want to reduce
 the default memory requirements from 256K to 128K, compile with
     make CFLAGS="-O -DMAX_WBITS=14 -DMAX_MEM_LEVEL=7"
 Of course this will generally degrade compression (there's no free lunch).

   The memory requirements for inflate are (in bytes) 1 << windowBits
```

```
 that is, 32K for windowBits=15 (default value) plus a few kilobytes
 for small objects.

.TH LIBZ 3 "28 Apr 2013"
.SH NAME
libz \- compression/decompression library
.SH SYNOPSIS
[see
.I zlib.h
for full description]
.SH DESCRIPTION
The
.I libz (zlib)
library is a general purpose data compression library.
The code is thread safe, assuming that the standard library functions
used are thread safe, such as memory allocation routines.
It provides in-memory compression and decompression functions,
including integrity checks of the uncompressed data.
This version of the library supports only one compression method (deflation)
but other algorithms may be added later
with the same stream interface.
.LP
Compression can be done in a single step if the buffers are large enough
or can be done by repeated calls of the compression function.
In the latter case,
the application must provide more input and/or consume the output
(providing more output space) before each call.
.LP
The library also supports reading and writing files in
.IR gzip (1)
(.gz) format
with an interface similar to that of stdio.
.LP
The library does not install any signal handler.
The decoder checks the consistency of the compressed data,
so the library should never crash even in the case of corrupted input.
.LP
All functions of the compression library are documented in the file
.IR zlib.h .
The distribution source includes examples of use of the library
in the files
.I test/example.c
and
.IR test/minigzip.c,
as well as other examples in the
.IR examples/
directory.
.LP
Changes to this version are documented in the file
.I ChangeLog
that accompanies the source.
.LP
.I zlib
is available in Java using the java.util.zip package:
.IP
http://java.sun.com/developer/technicalArticles/Programming/compression/
.LP
A Perl interface to
.IR zlib ,
written by Paul Marquess (pmqs@cpan.org),
is available at CPAN (Comprehensive Perl Archive Network) sites,
including:
.IP
```

```
http://search.cpan.org/~pmqs/IO-Compress-Zlib/
.LP
A Python interface to
.IR zlib ,
written by A.M. Kuchling (amk@magnet.com),
is available in Python 1.5 and later versions:
.IP
http://docs.python.org/library/zlib.html
.LP
.I zlib
is built into
.IR tcl:

#define ZLIB_VER_SUBREVISION 0

/*
    The 'zlib' compression library provides in-memory compression and
  decompression functions, including integrity checks of the uncompressed data.
  This version of the library supports only one compression method (deflation)
  but other algorithms will be added later and will have the same stream
  interface.

    Compression can be done in a single step if the buffers are large enough,
  or can be done by repeated calls of the compression function.  In the latter
  case, the application must provide more input and/or consume the output
  (providing more output space) before each call.

    The compressed data format used by default by the in-memory functions is
  the zlib format, which is a zlib wrapper documented in RFC 1950, wrapped
```

```
  around a deflate stream, which is itself documented in RFC 1951.

    The library also supports reading and writing files in gzip (.gz) format
  with an interface similar to that of stdio using the functions that start
  with "gz".  The gzip format is different from the zlib format.  gzip is a
  gzip wrapper, documented in RFC 1952, wrapped around a deflate stream.

    This library can optionally read and write gzip streams in memory as well.

    The zlib format was designed to be compact and fast for use in memory
  and on communications channels.  The gzip format was designed for single-
  file compression on file systems, has a larger header than zlib to maintain
  directory information, and uses a different, slower check method than zlib.

    The library does not install any signal handler.  The decoder checks
  the consistency of the compressed data, so the library should never crash
  even in case of corrupted input.

typedef gz_header FAR *gz_headerp;

/*
     The application must update next_in and avail_in when avail_in has dropped
   to zero.  It must update next_out and avail_out when avail_out has dropped
   to zero.  The application must initialize zalloc, zfree and opaque before
   calling the init function.  All other fields are set by the compression
   library and must not be updated by the application.

     The opaque value provided by the application will be passed as the first
   parameter for calls of zalloc and zfree.  This can be useful for custom
   memory management.  The compression library attaches no meaning to the
   opaque value.

     zalloc must return Z_NULL if there is not enough memory for the object.
   If zlib is used in a multi-threaded application, zalloc and zfree must be
   thread safe.

     On 16-bit systems, the functions zalloc and zfree must be able to allocate
   exactly 65536 bytes, but will not be required to allocate more than this if
   the symbol MAXSEG_64K is defined (see zconf.h).  WARNING: On MSDOS, pointers
   returned by zalloc for objects of exactly 65536 bytes *must* have their
   offset normalized to zero.  The default allocation function provided by this
   library ensures this (see zutil.c).  To reduce memory requirements and avoid
   any allocation of 64K objects, at the expense of compression ratio, compile
   the library with -DMAX_WBITS=14 (see zconf.h).

     The fields total_in and total_out can be used for statistics or progress
   reports.  After compression, total_in holds the total size of the
   uncompressed data and may be saved for use in the decompressor (particularly
   if the decompressor wants to decompress everything in a single step).

 */

/*
ZEXTERN int ZEXPORT deflateInit OF((z_streamp strm, int level));

     Initializes the internal stream state for compression.  The fields
   zalloc, zfree and opaque must be initialized before by the caller.  If
   zalloc and zfree are set to Z_NULL, deflateInit updates them to use default
   allocation functions.

     The compression level must be Z_DEFAULT_COMPRESSION, or between 0 and 9:
   1 gives best speed, 9 gives best compression, 0 gives no compression at all
   (the input data is simply copied a block at a time).  Z_DEFAULT_COMPRESSION
   requests a default compromise between speed and compression (currently
   equivalent to level 6).

     deflateInit returns Z_OK if success, Z_MEM_ERROR if there was not enough
   memory, Z_STREAM_ERROR if level is not a valid compression level, or
   Z_VERSION_ERROR if the zlib library version (zlib_version) is incompatible
   with the version assumed by the caller (ZLIB_VERSION).  msg is set to null
   if there is no error message.  deflateInit does not perform any compression:
   this will be done by deflate().
*/

ZEXTERN int ZEXPORT deflate OF((z_streamp strm, int flush));
/*
    deflate compresses as much data as possible, and stops when the input
  buffer becomes empty or the output buffer becomes full.  It may introduce
  some output latency (reading input without producing any output) except when
  forced to flush.

    The detailed semantics are as follows.  deflate performs one or both of the
  following actions:

  - Compress more input starting at next_in and update next_in and avail_in
    accordingly.  If not all input can be processed (because there is not
    enough room in the output buffer), next_in and avail_in are updated and
```

```
259     processing will resume at this point for the next call of deflate().
260
261   - Provide more output starting at next_out and update next_out and avail_out
262     accordingly.  This action is forced if the parameter flush is non zero.
263     Forcing flush frequently degrades the compression ratio, so this parameter
264     should be set only when necessary (in interactive applications).  Some
265     output may be provided even if flush is not set.
266
267     Before the call of deflate(), the application should ensure that at least
268   one of the actions is possible, by providing more input and/or consuming more
269   output, and updating avail_in or avail_out accordingly; avail_out should
270   never be zero before the call.  The application can consume the compressed
271   output when it wants, for example when the output buffer is full (avail_out
272   == 0), or after each call of deflate().  If deflate returns Z_OK and with
273   zero avail_out, it must be called again after making room in the output
274   buffer because there might be more output pending.
275
276     Normally the parameter flush is set to Z_NO_FLUSH, which allows deflate to
277   decide how much data to accumulate before producing output, in order to
278   maximize compression.
279
280     If the parameter flush is set to Z_SYNC_FLUSH, all pending output is
281   flushed to the output buffer and the output is aligned on a byte boundary, so
282   that the decompressor can get all input data available so far.  (In
283   particular avail_in is zero after the call if enough output space has been
284   provided before the call.) Flushing may degrade compression for some
285   compression algorithms and so it should be used only when necessary.  This
286   completes the current deflate block and follows it with an empty stored block
287   that is three bits plus filler bits to the next byte, followed by four bytes
288   (00 00 ff ff).
289
290     If flush is set to Z_PARTIAL_FLUSH, all pending output is flushed to the
291   output buffer, but the output is not aligned to a byte boundary.  All of the
292   input data so far will be available to the decompressor, as for Z_SYNC_FLUSH.
293   This completes the current deflate block and follows it with an empty fixed
294   codes block that is 10 bits long.  This assures that enough bytes are output
295   in order for the decompressor to finish the block before the empty fixed code
296   block.
297
298     If flush is set to Z_BLOCK, a deflate block is completed and emitted, as
299   for Z_SYNC_FLUSH, but the output is not aligned on a byte boundary, and up to
300   seven bits of the current block are held to be written as the next byte after
301   the next deflate block is completed.  In this case, the decompressor may not
302   be provided enough bits at this point in order to complete decompression of
303   the data provided so far to the compressor.  It may need to wait for the next
304   block to be emitted.  This is for advanced applications that need to control
305   the emission of deflate blocks.
306
307     If flush is set to Z_FULL_FLUSH, all output is flushed as with
308   Z_SYNC_FLUSH, and the compression state is reset so that decompression can
309   restart from this point if previous compressed data has been damaged or if
310   random access is desired.  Using Z_FULL_FLUSH too often can seriously degrade
311   compression.
312
313     If deflate returns with avail_out == 0, this function must be called again
314   with the same value of the flush parameter and more output space (updated
315   avail_out), until the flush is complete (deflate returns with non-zero
316   avail_out).  In the case of a Z_FULL_FLUSH or Z_SYNC_FLUSH, make sure that
317   avail_out is greater than six to avoid repeated flush markers due to
318   avail_out == 0 on return.
319
320     If the parameter flush is set to Z_FINISH, pending input is processed,
321   pending output is flushed and deflate returns with Z_STREAM_END if there was
322   enough output space; if deflate returns with Z_OK, this function must be
323   called again with Z_FINISH and more output space (updated avail_out) but no
324   more input data, until it returns with Z_STREAM_END or an error.  After
```

```
325   deflate has returned Z_STREAM_END, the only possible operations on the stream
326   are deflateReset or deflateEnd.
327
328     Z_FINISH can be used immediately after deflateInit if all the compression
329   is to be done in a single step.  In this case, avail_out must be at least the
330   value returned by deflateBound (see below).  Then deflate is guaranteed to
331   return Z_STREAM_END.  If not enough output space is provided, deflate will
332   not return Z_STREAM_END, and it must be called again as described above.
333
334     deflate() sets strm->adler to the adler32 checksum of all input read
335   so far (that is, total_in bytes).
336
337     deflate() may update strm->data_type if it can make a good guess about
338   the input data type (Z_BINARY or Z_TEXT).  In doubt, the data is considered
339   binary.  This field is only for information purposes and does not affect the
340   compression algorithm in any manner.
341
342     deflate() returns Z_OK if some progress has been made (more input
343   processed or more output produced), Z_STREAM_END if all input has been
344   consumed and all output has been produced (only when flush is set to
345   Z_FINISH), Z_STREAM_ERROR if the stream state was inconsistent (for example
346   if next_in or next_out was Z_NULL), Z_BUF_ERROR if no progress is possible
347   (for example avail_in or avail_out was zero).  Note that Z_BUF_ERROR is not
348   fatal, and deflate() can be called again with more input and more output
349   space to continue compressing.
350 */
351
352
353 ZEXTERN int ZEXPORT deflateEnd OF((z_streamp strm));
354 /*
355      All dynamically allocated data structures for this stream are freed.
356    This function discards any unprocessed input and does not flush any pending
357    output.
358
359      deflateEnd returns Z_OK if success, Z_STREAM_ERROR if the
360    stream state was inconsistent, Z_DATA_ERROR if the stream was freed
361    prematurely (some input or output was discarded).  In the error case, msg
362    may be set but then points to a static string (which must not be
363    deallocated).
364 */
365
366
367 /*
368 ZEXTERN int ZEXPORT inflateInit OF((z_streamp strm));
369
370      Initializes the internal stream state for decompression.  The fields
371    next_in, avail_in, zalloc, zfree and opaque must be initialized before by
372    the caller.  If next_in is not Z_NULL and avail_in is large enough (the
373    exact value depends on the compression method), inflateInit determines the
374    compression method from the zlib header and allocates all data structures
375    accordingly; otherwise the allocation will be deferred to the first call of
376    inflate.  If zalloc and zfree are set to Z_NULL, inflateInit updates them to
377    use default allocation functions.
378
379      inflateInit returns Z_OK if success, Z_MEM_ERROR if there was not enough
380    memory, Z_VERSION_ERROR if the zlib library version is incompatible with the
381    version assumed by the caller, or Z_STREAM_ERROR if the parameters are
382    invalid, such as a null pointer to the structure.  msg is set to null if
383    there is no error message.  inflateInit does not perform any decompression
384    apart from possibly reading the zlib header if present: actual decompression
385    will be done by inflate().  (So next_in and avail_in may be modified, but
386    next_out and avail_out are unused and unchanged.) The current implementation
387    of inflateInit() does not process any header information -- that is deferred
388    until inflate() is called.
389 */
```

```
ZEXTERN int ZEXPORT inflate OF((z_streamp strm, int flush));
/*
     inflate decompresses as much data as possible, and stops when the input
   buffer becomes empty or the output buffer becomes full.  It may introduce
   some output latency (reading input without producing any output) except when
   forced to flush.

   The detailed semantics are as follows.  inflate performs one or both of the
   following actions:

   - Decompress more input starting at next_in and update next_in and avail_in
     accordingly.  If not all input can be processed (because there is not
     enough room in the output buffer), next_in is updated and processing will
     resume at this point for the next call of inflate().

   - Provide more output starting at next_out and update next_out and avail_out
     accordingly.  inflate() provides as much output as possible, until there is
     no more input data or no more space in the output buffer (see below about
     the flush parameter).

     Before the call of inflate(), the application should ensure that at least
   one of the actions is possible, by providing more input and/or consuming more
   output, and updating the next_* and avail_* values accordingly.  The
   application can consume the uncompressed output when it wants, for example
   when the output buffer is full (avail_out == 0), or after each call of
   inflate().  If inflate returns Z_OK and with zero avail_out, it must be
   called again after making room in the output buffer because there might be
   more output pending.

     The flush parameter of inflate() can be Z_NO_FLUSH, Z_SYNC_FLUSH, Z_FINISH,
   Z_BLOCK, or Z_TREES.  Z_SYNC_FLUSH requests that inflate() flush as much
   output as possible to the output buffer.  Z_BLOCK requests that inflate()
   stop if and when it gets to the next deflate block boundary.  When decoding
   the zlib or gzip format, this will cause inflate() to return immediately
   after the header and before the first block.  When doing a raw inflate,
   inflate() will go ahead and process the first block, and will return when it
   gets to the end of that block, or when it runs out of data.

     The Z_BLOCK option assists in appending to or combining deflate streams.
   Also to assist in this, on return inflate() will set strm->data_type to the
   number of unused bits in the last byte taken from strm->next_in, plus 64 if
   inflate() is currently decoding the last block in the deflate stream, plus
   128 if inflate() returned immediately after decoding an end-of-block code or
   decoding the complete header up to just before the first byte of the deflate
   stream.  The end-of-block will not be indicated until all of the uncompressed
   data from that block has been written to strm->next_out.  The number of
   unused bits may in general be greater than seven, except when bit 7 of
   data_type is set, in which case the number of unused bits will be less than
   eight.  data_type is set as noted here every time inflate() returns for all
   flush options, and so can be used to determine the amount of currently
   consumed input in bits.

     The Z_TREES option behaves as Z_BLOCK does, but it also returns when the
   end of each deflate block header is reached, before any actual data in that
   block is decoded.  This allows the caller to determine the length of the
   deflate block header for later use in random access within a deflate block.
   256 is added to the value of strm->data_type when inflate() returns
   immediately after reaching the end of the deflate block header.

     inflate() should normally be called until it returns Z_STREAM_END or an
   error.  However if all decompression is to be performed in a single step (a
   single call of inflate), the parameter flush should be set to Z_FINISH.  In
   this case all pending input is processed and all pending output is flushed;
   avail_out must be large enough to hold all of the uncompressed data for the
   operation to complete.  (The size of the uncompressed data may have been
```

```
   saved by the compressor for this purpose.) The use of Z_FINISH is not
   required to perform an inflation in one step.  However it may be used to
   inform inflate that a faster approach can be used for the single inflate()
   call.  Z_FINISH also informs inflate to not maintain a sliding window if the
   stream completes, which reduces inflate's memory footprint.  If the stream
   does not complete, either because not all of the stream is provided or not
   enough output space is provided, then a sliding window will be allocated and
   inflate() can be called again to continue the operation as if Z_NO_FLUSH had
   been used.

      In this implementation, inflate() always flushes as much output as
   possible to the output buffer, and always uses the faster approach on the
   first call.  So the effects of the flush parameter in this implementation are
   on the return value of inflate() as noted below, when inflate() returns early
   when Z_BLOCK or Z_TREES is used, and when inflate() avoids the allocation of
   memory for a sliding window when Z_FINISH is used.

     If a preset dictionary is needed after this call (see inflateSetDictionary
   below), inflate sets strm->adler to the Adler-32 checksum of the dictionary
   chosen by the compressor and returns Z_NEED_DICT; otherwise it sets
   strm->adler to the Adler-32 checksum of all output produced so far (that is,
   total_out bytes) and returns Z_OK, Z_STREAM_END or an error code as described
   below.  At the end of the stream, inflate() checks that its computed adler32
   checksum is equal to that saved by the compressor and returns Z_STREAM_END
   only if the checksum is correct.

     inflate() can decompress and check either zlib-wrapped or gzip-wrapped
   deflate data.  The header type is detected automatically, if requested when
   initializing with inflateInit2().  Any information contained in the gzip
   header is not retained, so applications that need that information should
   instead use raw inflate, see inflateInit2() below, or inflateBack() and
   perform their own processing of the gzip header and trailer.  When processing
   gzip-wrapped deflate data, strm->adler32 is set to the CRC-32 of the output
   producted so far.  The CRC-32 is checked against the gzip trailer.

     inflate() returns Z_OK if some progress has been made (more input processed
   or more output produced), Z_STREAM_END if the end of the compressed data has
   been reached and all uncompressed output has been produced, Z_NEED_DICT if a
   preset dictionary is needed at this point, Z_DATA_ERROR if the input data was
   corrupted (input stream not conforming to the zlib format or incorrect check
   value), Z_STREAM_ERROR if the stream structure was inconsistent (for example
   next_in or next_out was Z_NULL), Z_MEM_ERROR if there was not enough memory,
   Z_BUF_ERROR if no progress is possible or if there was not enough room in the
   output buffer when Z_FINISH is used.  Note that Z_BUF_ERROR is not fatal, and
   inflate() can be called again with more input and more output space to
   continue decompressing.  If Z_DATA_ERROR is returned, the application may
   then call inflateSync() to look for a good compression block if a partial
   recovery of the data is desired.
*/

ZEXTERN int ZEXPORT inflateEnd OF((z_streamp strm));

530                                      int  windowBits,
531                                      int  memLevel,
532                                      int  strategy));
533
534     This is another version of deflateInit with more compression options.  The
535   fields next_in, zalloc, zfree and opaque must be initialized before by the
536   caller.
537
538     The method parameter is the compression method.  It must be Z_DEFLATED in
539   this version of the library.
540
541     The windowBits parameter is the base two logarithm of the window size
542   (the size of the history buffer).  It should be in the range 8..15 for this
543   version of the library.  Larger values of this parameter result in better
544   compression at the expense of memory usage.  The default value is 15 if
545   deflateInit is used instead.
546
547     windowBits can also be -8..-15 for raw deflate.  In this case, -windowBits
548   determines the window size.  deflate() will then generate raw deflate data
549   with no zlib header or trailer, and will not compute an adler32 check value.
550
551     windowBits can also be greater than 15 for optional gzip encoding.  Add
552   16 to windowBits to write a simple gzip header and trailer around the
553   compressed data instead of a zlib wrapper.  The gzip header will have no
554   file name, no extra data, no comment, no modification time (set to zero), no
555   header crc, and the operating system will be set to 255 (unknown).  If a
556   gzip stream is being written, strm->adler is a crc32 instead of an adler32.
557
558     The memLevel parameter specifies how much memory should be allocated
559   for the internal compression state.  memLevel=1 uses minimum memory but is
560   slow and reduces compression ratio; memLevel=9 uses maximum memory for
561   optimal speed.  The default value is 8.  See zconf.h for total memory usage
562   as a function of windowBits and memLevel.
563
564     The strategy parameter is used to tune the compression algorithm.  Use the
565   value Z_DEFAULT_STRATEGY for normal data, Z_FILTERED for data produced by a
566   filter (or predictor), Z_HUFFMAN_ONLY to force Huffman encoding only (no
567   string match), or Z_RLE to limit match distances to one (run-length
568   encoding).  Filtered data consists mostly of small values with a somewhat
569   random distribution.  In this case, the compression algorithm is tuned to
570   compress them better.  The effect of Z_FILTERED is to force more Huffman
571   coding and less string matching; it is somewhat intermediate between
572   Z_DEFAULT_STRATEGY and Z_HUFFMAN_ONLY.  Z_RLE is designed to be almost as
573   fast as Z_HUFFMAN_ONLY, but give better compression for PNG image data.  The
574   strategy parameter only affects the compression ratio but not the
575   correctness of the compressed output even if it is not set appropriately.
576   Z_FIXED prevents the use of dynamic Huffman codes, allowing for a simpler
577   decoder for special applications.
578
579     deflateInit2 returns Z_OK if success, Z_MEM_ERROR if there was not enough
580   memory, Z_STREAM_ERROR if any parameter is invalid (such as an invalid
581   method), or Z_VERSION_ERROR if the zlib library version (zlib_version) is
582   incompatible with the version assumed by the caller (ZLIB_VERSION).  msg is
583   set to null if there is no error message.  deflateInit2 does not perform any
584   compression: this will be done by deflate().
585 */
586
587 ZEXTERN int ZEXPORT deflateSetDictionary OF((z_streamp strm,
588                                              const Bytef *dictionary,
```

```
589                                              uInt  dictLength));
590 /*
591     Initializes the compression dictionary from the given byte sequence
592   without producing any compressed output.  When using the zlib format, this
593   function must be called immediately after deflateInit, deflateInit2 or
594   deflateReset, and before any call of deflate.  When doing raw deflate, this
595   function must be called either before any call of deflate, or immediately
596   after the completion of a deflate block, i.e. after all input has been
597   consumed and all output has been delivered when using any of the flush
598   options Z_BLOCK, Z_PARTIAL_FLUSH, Z_SYNC_FLUSH, or Z_FULL_FLUSH.  The
599   compressor and decompressor must use exactly the same dictionary (see
600   inflateSetDictionary).
601
602     The dictionary should consist of strings (byte sequences) that are likely
603   to be encountered later in the data to be compressed, with the most commonly
604   used strings preferably put towards the end of the dictionary.  Using a
605   dictionary is most useful when the data to be compressed is short and can be
606   predicted with good accuracy; the data can then be compressed better than
607   with the default empty dictionary.
608
609     Depending on the size of the compression data structures selected by
610   deflateInit or deflateInit2, a part of the dictionary may in effect be
611   discarded, for example if the dictionary is larger than the window size
612   provided in deflateInit or deflateInit2.  Thus the strings most likely to be
613   useful should be put at the end of the dictionary, not at the front.  In
614   addition, the current implementation of deflate will use at most the window
615   size minus 262 bytes of the provided dictionary.
616
617     Upon return of this function, strm->adler is set to the adler32 value
618   of the dictionary; the decompressor may later use this value to determine
619   which dictionary has been used by the compressor.  (The adler32 value
620   applies to the whole dictionary even if only a subset of the dictionary is
621   actually used by the compressor.) If a raw deflate was requested, then the
622   adler32 value is not computed and strm->adler is not set.
623
624     deflateSetDictionary returns Z_OK if success, or Z_STREAM_ERROR if a
625   parameter is invalid (e.g.  dictionary being Z_NULL) or the stream state is
626   inconsistent (for example if deflate has already been called for this stream
627   or if not at a block boundary for raw deflate).  deflateSetDictionary does
628   not perform any compression: this will be done by deflate().
629 */
630
631 ZEXTERN int ZEXPORT deflateCopy OF((z_streamp dest,
632                                     z_streamp source));
633 /*
634     Sets the destination stream as a complete copy of the source stream.
635
636     This function can be useful when several compression strategies will be
637   tried, for example when there are several ways of pre-processing the input
638   data with a filter.  The streams that will be discarded should then be freed
639   by calling deflateEnd.  Note that deflateCopy duplicates the internal
640   compression state which can be quite large, so this strategy is slow and can
641   consume lots of memory.
642
643     deflateCopy returns Z_OK if success, Z_MEM_ERROR if there was not
644   enough memory, Z_STREAM_ERROR if the source stream state was inconsistent
645   (such as zalloc being Z_NULL).  msg is left unchanged in both source and
646   destination.
647 */
648
649 ZEXTERN int ZEXPORT deflateReset OF((z_streamp strm));
650 /*
651     This function is equivalent to deflateEnd followed by deflateInit,
652   but does not free and reallocate all the internal compression state.  The
653   stream will keep the same compression level and any other attributes that
654   may have been set by deflateInit2.
```

```
656      deflateReset returns Z_OK if success, or Z_STREAM_ERROR if the source
657    stream state was inconsistent (such as zalloc or state being Z_NULL).
658 */
659
660 ZEXTERN int ZEXPORT deflateParams OF((z_streamp strm,
661                                       int level,
662                                       int strategy));
663 /*
664      Dynamically update the compression level and compression strategy.  The
665    interpretation of level and strategy is as in deflateInit2.  This can be
666    used to switch between compression and straight copy of the input data, or
667    to switch to a different kind of input data requiring a different strategy.
668    If the compression level is changed, the input available so far is
669    compressed with the old level (and may be flushed); the new level will take
670    effect only at the next call of deflate().
671
672      Before the call of deflateParams, the stream state must be set as for
673    a call of deflate(), since the currently available input may have to be
674    compressed and flushed.  In particular, strm->avail_out must be non-zero.
675
676      deflateParams returns Z_OK if success, Z_STREAM_ERROR if the source
677    stream state was inconsistent or if a parameter was invalid, Z_BUF_ERROR if
678    strm->avail_out was zero.
679 */

714                                        unsigned *pending,
715                                        int *bits));
716 /*
717      deflatePending() returns the number of bytes and bits of output that have
718    been generated, but not yet provided in the available output.  The bytes not
719    provided would be due to the available output space having being consumed.
720    The number of bits of output not provided are between 0 and 7, where they
```

```
721    await more bits to join them in order to fill out a full byte.  If pending
722    or bits are Z_NULL, then those values are not set.
723
724      deflatePending returns Z_OK if success, or Z_STREAM_ERROR if the source
725    stream state was inconsistent.
726  */
727
728 ZEXTERN int ZEXPORT deflatePrime OF((z_streamp strm,
729                                      int bits,
730                                      int value));
731 /*
732      deflatePrime() inserts bits in the deflate output stream.  The intent
733    is that this function is used to start off the deflate output with the bits
734    leftover from a previous deflate stream when appending to it.  As such, this
735    function can only be used for raw deflate, and must be used before the first
736    deflate() call after a deflateInit2() or deflateReset().  bits must be less
737    than or equal to 16, and that many of the least significant bits of value
738    will be inserted in the output.
739
740      deflatePrime returns Z_OK if success, Z_BUF_ERROR if there was not enough
741    room in the internal buffer to insert the bits, or Z_STREAM_ERROR if the
742    source stream state was inconsistent.
743 */
744
745 ZEXTERN int ZEXPORT deflateSetHeader OF((z_streamp strm,
746                                          gz_headerp head));
747 /*
748      deflateSetHeader() provides gzip header information for when a gzip
749    stream is requested by deflateInit2().  deflateSetHeader() may be called
750    after deflateInit2() or deflateReset() and before the first call of
751    deflate().  The text, time, os, extra field, name, and comment information
752    in the provided gz_header structure are written to the gzip header (xflag is
753    ignored -- the extra flags are set according to the compression level).  The
754    caller must assure that, if not Z_NULL, name and comment are terminated with
755    a zero byte, and that if extra is not Z_NULL, that extra_len bytes are
756    available there.  If hcrc is true, a gzip header crc is included.  Note that
757    the current versions of the command-line version of gzip (up through version
758    1.3.x) do not support header crc's, and will report that it is a "multi-part
759    gzip file" and give up.
760
761      If deflateSetHeader is not used, the default gzip header has text false,
762    the time set to zero, and os set to 255, with no extra, name, or comment
763    fields.  The gzip header is returned to the default state by deflateReset().
764
765      deflateSetHeader returns Z_OK if success, or Z_STREAM_ERROR if the source
766    stream state was inconsistent.
767 */
768
769 /*
770 ZEXTERN int ZEXPORT inflateInit2 OF((z_streamp strm,
771                                      int  windowBits));
772
773      This is another version of inflateInit with an extra parameter.  The
774    fields next_in, avail_in, zalloc, zfree and opaque must be initialized
775    before by the caller.
776
777      The windowBits parameter is the base two logarithm of the maximum window
778    size (the size of the history buffer).  It should be in the range 8..15 for
779    this version of the library.  The default value is 15 if inflateInit is used
780    instead.  windowBits must be greater than or equal to the windowBits value
781    provided to deflateInit2() while compressing, or it must be equal to 15 if
782    deflateInit2() was not used.  If a compressed stream with a larger window
783    size is given as input, inflate() will return with the error code
784    Z_DATA_ERROR instead of trying to allocate a larger window.
785
786      windowBits can also be zero to request that inflate use the window size in
```

```
787    the zlib header of the compressed stream.
788
789      windowBits can also be -8..-15 for raw inflate.  In this case, -windowBits
790    determines the window size.  inflate() will then process raw deflate data,
791    not looking for a zlib or gzip header, not generating a check value, and not
792    looking for any check values for comparison at the end of the stream.  This
793    is for use with other formats that use the deflate compressed data format
794    such as zip.  Those formats provide their own check values.  If a custom
795    format is developed using the raw deflate format for compressed data, it is
796    recommended that a check value such as an adler32 or a crc32 be applied to
797    the uncompressed data as is done in the zlib, gzip, and zip formats.  For
798    most applications, the zlib format should be used as is.  Note that comments
799    above on the use in deflateInit2() applies to the magnitude of windowBits.
800
801      windowBits can also be greater than 15 for optional gzip decoding.  Add
802    32 to windowBits to enable zlib and gzip decoding with automatic header
803    detection, or add 16 to decode only the gzip format (the zlib format will
804    return a Z_DATA_ERROR).  If a gzip stream is being decoded, strm->adler is a
805    crc32 instead of an adler32.
806
807      inflateInit2 returns Z_OK if success, Z_MEM_ERROR if there was not enough
808    memory, Z_VERSION_ERROR if the zlib library version is incompatible with the
809    version assumed by the caller, or Z_STREAM_ERROR if the parameters are
810    invalid, such as a null pointer to the structure.  msg is set to null if
811    there is no error message.  inflateInit2 does not perform any decompression
812    apart from possibly reading the zlib header if present: actual decompression
813    will be done by inflate().  (So next_in and avail_in may be modified, but
814    next_out and avail_out are unused and unchanged.) The current implementation
815    of inflateInit2() does not process any header information -- that is
816    deferred until inflate() is called.
817 */

819 ZEXTERN int ZEXPORT inflateSetDictionary OF((z_streamp strm,
820                                              const Bytef *dictionary,
821                                              uInt  dictLength));
822 /*
823      Initializes the decompression dictionary from the given uncompressed byte
824    sequence.  This function must be called immediately after a call of inflate,
825    if that call returned Z_NEED_DICT.  The dictionary chosen by the compressor
826    can be determined from the adler32 value returned by that call of inflate.
827    The compressor and decompressor must use exactly the same dictionary (see
828    deflateSetDictionary).  For raw inflate, this function can be called at any
829    time to set the dictionary.  If the provided dictionary is smaller than the
830    window and there is already data in the window, then the provided dictionary
831    will amend what's there.  The application must insure that the dictionary
832    that was used for compression is provided.
833
834      inflateSetDictionary returns Z_OK if success, Z_STREAM_ERROR if a
835    parameter is invalid (e.g.  dictionary being Z_NULL) or the stream state is
836    inconsistent, Z_DATA_ERROR if the given dictionary doesn't match the
837    expected one (incorrect adler32 value).  inflateSetDictionary does not
838    perform any decompression: this will be done by subsequent calls of
839    inflate().
840 */
841
842 ZEXTERN int ZEXPORT inflateGetDictionary OF((z_streamp strm,
843                                              Bytef *dictionary,
844                                              uInt  *dictLength));
845 /*
846      Returns the sliding dictionary being maintained by inflate.  dictLength is
847    set to the number of bytes in the dictionary, and that many bytes are copied
848    to dictionary.  dictionary must have enough space, where 32768 bytes is
849    always enough.  If inflateGetDictionary() is called with dictionary equal to
850    Z_NULL, then only the dictionary length is returned, and nothing is copied.
851    Similary, if dictLength is Z_NULL, then it is not set.
```

```
853      inflateGetDictionary returns Z_OK on success, or Z_STREAM_ERROR if the
854    stream state is inconsistent.

903                                       int windowBits));
904 /*
905      This function is the same as inflateReset, but it also permits changing
906    the wrap and window size requests.  The windowBits parameter is interpreted
907    the same as it is for inflateInit2.
908
909      inflateReset2 returns Z_OK if success, or Z_STREAM_ERROR if the source
910    stream state was inconsistent (such as zalloc or state being Z_NULL), or if
911    the windowBits parameter is invalid.
912 */
913
914 ZEXTERN int ZEXPORT inflatePrime OF((z_streamp strm,
915                                      int bits,
916                                      int value));
917 /*
918      This function inserts bits in the inflate input stream.  The intent is
```

```
   that this function is used to start inflating at a bit position in the
   middle of a byte.  The provided bits will be used before any bytes are used
   from next_in.  This function should only be used with raw inflate, and
   should be used before the first inflate() call after inflateInit2() or
   inflateReset().  bits must be less than or equal to 16, and that many of the
   least significant bits of value will be inserted in the input.

     If bits is negative, then the input stream bit buffer is emptied.  Then
   inflatePrime() can be called again to put bits in the buffer.  This is used
   to clear out bits leftover after feeding inflate a block description prior
   to feeding inflate codes.

     inflatePrime returns Z_OK if success, or Z_STREAM_ERROR if the source
   stream state was inconsistent.
*/

ZEXTERN long ZEXPORT inflateMark OF((z_streamp strm));
/*
     This function returns two values, one in the lower 16 bits of the return
   value, and the other in the remaining upper bits, obtained by shifting the
   return value down 16 bits.  If the upper value is -1 and the lower value is
   zero, then inflate() is currently decoding information outside of a block.
   If the upper value is -1 and the lower value is non-zero, then inflate is in
   the middle of a stored block, with the lower value equaling the number of
   bytes from the input remaining to copy.  If the upper value is not -1, then
   it is the number of bits back from the current bit position in the input of
   the code (literal or length/distance pair) currently being processed.  In
   that case the lower value is the number of bytes already emitted for that
   code.

     A code is being processed if inflate is waiting for more input to complete
   decoding of the code, or if it has completed decoding but is waiting for
   more output space to write the literal or match data.

     inflateMark() is used to mark locations in the input data for random
   access, which may be at bit positions, and to note those cases where the
   output of a code may span boundaries of random access blocks.  The current
   location in the input stream can be determined from avail_in and data_type
   as noted in the description for the Z_BLOCK flush parameter for inflate.

     inflateMark returns the value noted above or -1 << 16 if the provided
   source stream state was inconsistent.
*/

ZEXTERN int ZEXPORT inflateGetHeader OF((z_streamp strm,
                                         gz_headerp head));
/*
     inflateGetHeader() requests that gzip header information be stored in the
   provided gz_header structure.  inflateGetHeader() may be called after
   inflateInit2() or inflateReset(), and before the first call of inflate().
   As inflate() processes the gzip stream, head->done is zero until the header
   is completed, at which time head->done is set to one.  If a zlib stream is
   being decoded, then head->done is set to -1 to indicate that there will be
   no gzip header information forthcoming.  Note that Z_BLOCK or Z_TREES can be
   used to force inflate() to return immediately after header processing is
   complete and before any actual data is decompressed.

     The text, time, xflags, and os fields are filled in with the gzip header
   contents.  hcrc is set to true if there is a header CRC.  (The header CRC
   was valid if done is set to one.) If extra is not Z_NULL, then extra_max
   contains the maximum number of bytes to write to extra.  Once done is true,
   extra_len contains the actual extra field length, and extra contains the
   extra field, or that field truncated if extra_max is less than extra_len.
   If name is not Z_NULL, then up to name_max characters are written there,
   terminated with a zero unless the length is greater than name_max.  If
   comment is not Z_NULL, then up to comm_max characters are written there,
```

```
   terminated with a zero unless the length is greater than comm_max.  When any
   of extra, name, or comment are not Z_NULL and the respective field is not
   present in the header, then that field is set to Z_NULL to signal its
   absence.  This allows the use of deflateSetHeader() with the returned
   structure to duplicate the header.  However if those fields are set to
   allocated memory, then the application will need to save those pointers
   elsewhere so that they can be eventually freed.

     If inflateGetHeader is not used, then the header information is simply
   discarded.  The header is always checked for validity, including the header
   CRC if present.  inflateReset() will reset the process to discard the header
   information.  The application would need to call inflateGetHeader() again to
   retrieve the header from the next gzip stream.

     inflateGetHeader returns Z_OK if success, or Z_STREAM_ERROR if the source
   stream state was inconsistent.
*/

/*
ZEXTERN int ZEXPORT inflateBackInit OF((z_streamp strm, int windowBits,
                                        unsigned char FAR *window));

     Initialize the internal stream state for decompression using inflateBack()
   calls.  The fields zalloc, zfree and opaque in strm must be initialized
   before the call.  If zalloc and zfree are Z_NULL, then the default library-
   derived memory allocation routines are used.  windowBits is the base two
   logarithm of the window size, in the range 8..15.  window is a caller
   supplied buffer of that size.  Except for special applications where it is
   assured that deflate was used with small window sizes, windowBits must be 15
   and a 32K byte window must be supplied to be able to decompress general
   deflate streams.

     See inflateBack() for the usage of these routines.

     inflateBackInit will return Z_OK on success, Z_STREAM_ERROR if any of
   the parameters are invalid, Z_MEM_ERROR if the internal state could not be
   allocated, or Z_VERSION_ERROR if the version of the library does not match
   the version of the header file.
*/

typedef unsigned (*in_func) OF((void FAR *,
                                z_const unsigned char FAR * FAR *));
typedef int (*out_func) OF((void FAR *, unsigned char FAR *, unsigned));

ZEXTERN int ZEXPORT inflateBack OF((z_streamp strm,
                                    in_func in, void FAR *in_desc,
                                    out_func out, void FAR *out_desc));
/*
     inflateBack() does a raw inflate with a single call using a call-back
   interface for input and output.  This is potentially more efficient than
   inflate() for file i/o applications, in that it avoids copying between the
   output and the sliding window by simply making the window itself the output
   buffer.  inflate() can be faster on modern CPUs when used with large
   buffers.  inflateBack() trusts the application to not change the output
   buffer passed by the output function, at least until inflateBack() returns.

     inflateBackInit() must be called first to allocate the internal state
   and to initialize the state with the user-provided window buffer.
   inflateBack() may then be used multiple times to inflate a complete, raw
   deflate stream with each call.  inflateBackEnd() is then called to free the
   allocated state.

     A raw deflate stream is one with no zlib or gzip header or trailer.
   This routine would normally be used in a utility that reads zip or gzip
   files and writes out uncompressed files.  The utility would decode the
   header and process the trailer on its own, hence this routine expects only
```

```
1051    the raw deflate stream to decompress.  This is different from the normal
1052    behavior of inflate(), which expects either a zlib or gzip header and
1053    trailer around the deflate stream.

1055      inflateBack() uses two subroutines supplied by the caller that are then
1056    called by inflateBack() for input and output.  inflateBack() calls those
1057    routines until it reads a complete deflate stream and writes out all of the
1058    uncompressed data, or until it encounters an error.  The function's
1059    parameters and return types are defined above in the in_func and out_func
1060    typedefs.  inflateBack() will call in(in_desc, &buf) which should return the
1061    number of bytes of provided input, and a pointer to that input in buf.  If
1062    there is no input available, in() must return zero--buf is ignored in that
1063    case--and inflateBack() will return a buffer error.  inflateBack() will call
1064    out(out_desc, buf, len) to write the uncompressed data buf[0..len-1].  out()
1065    should return zero on success, or non-zero on failure.  If out() returns
1066    non-zero, inflateBack() will return with an error.  Neither in() nor out()
1067    are permitted to change the contents of the window provided to
1068    inflateBackInit(), which is also the buffer that out() uses to write from.
1069    The length written by out() will be at most the window size.  Any non-zero
1070    amount of input may be provided by in().

1072      For convenience, inflateBack() can be provided input on the first call by
1073    setting strm->next_in and strm->avail_in.  If that input is exhausted, then
1074    in() will be called.  Therefore strm->next_in must be initialized before
1075    calling inflateBack().  If strm->next_in is Z_NULL, then in() will be called
1076    immediately for input.  If strm->next_in is not Z_NULL, then strm->avail_in
1077    must also be initialized, and then if strm->avail_in is not zero, input will
1078    initially be taken from strm->next_in[0 ..  strm->avail_in - 1].

1080      The in_desc and out_desc parameters of inflateBack() is passed as the
1081    first parameter of in() and out() respectively when they are called.  These
1082    descriptors can be optionally used to pass any information that the caller-
1083    supplied in() and out() functions need to do their job.

1085      On return, inflateBack() will set strm->next_in and strm->avail_in to
1086    pass back any unused input that was provided by the last in() call.  The
1087    return values of inflateBack() can be Z_STREAM_END on success, Z_BUF_ERROR
1088    if in() or out() returned an error, Z_DATA_ERROR if there was a format error
1089    in the deflate stream (in which case strm->msg is set to indicate the nature
1090    of the error), or Z_STREAM_ERROR if the stream was not properly initialized.
1091    In the case of Z_BUF_ERROR, an input or output error can be distinguished
1092    using strm->next_in which will be Z_NULL only if in() returned an error.  If
1093    strm->next_in is not Z_NULL, then the Z_BUF_ERROR was due to out() returning
1094    non-zero.  (in() will always be called before out(), so strm->next_in is
1095    assured to be defined if out() returns non-zero.) Note that inflateBack()
1096    cannot return Z_OK.

     Decompresses the source buffer into the destination buffer.  sourceLen is
   the byte length of the source buffer.  Upon entry, destLen is the total size
   of the destination buffer, which must be large enough to hold the entire
   uncompressed data.  (The size of the uncompressed data must have been saved
   previously by the compressor and transmitted to the decompressor by some
   mechanism outside the scope of this compression library.) Upon exit, destLen
   is the actual size of the uncompressed buffer.

     uncompress returns Z_OK if success, Z_MEM_ERROR if there was not
   enough memory, Z_BUF_ERROR if there was not enough room in the output
   buffer, or Z_DATA_ERROR if the input data was corrupted or incomplete.  In
   the case where there is not enough room, uncompress() will fill the output
   buffer with the uncompressed data up to that point.
*/

                        /* gzip file access functions */

/*
     This library supports reading and writing files in gzip (.gz) format with
   an interface similar to that of stdio, using the functions that start with
   "gz".  The gzip format is different from the zlib format.  gzip is a gzip
   wrapper, documented in RFC 1952, wrapped around a deflate stream.
*/

typedef struct gzFile_s *gzFile;    /* semi-opaque gzip file descriptor */

/*
ZEXTERN gzFile ZEXPORT gzopen OF((const char *path, const char *mode));

     Opens a gzip (.gz) file for reading or writing.  The mode parameter is as
   in fopen ("rb" or "wb") but can also include a compression level ("wb9") or
   a strategy: 'f' for filtered data as in "wb6f", 'h' for Huffman-only
   compression as in "wb1h", 'R' for run-length encoding as in "wb1R", or 'F'
   for fixed code compression as in "wb9F".  (See the description of
   deflateInit2 for more information about the strategy parameter.)  'T' will
   request transparent writing or appending with no compression and not using
   the gzip format.

     "a" can be used instead of "w" to request that the gzip stream that will
   be written be appended to the file.  "+" will result in an error, since
   reading and writing to the same gzip file is not supported.  The addition of
   "x" when writing will create the file exclusively, which fails if the file
   already exists.  On systems that support it, the addition of "e" when
   reading or writing will set the flag to close the file on an execve() call.

     These functions, as well as gzip, will read and decode a sequence of gzip
   streams in a file.  The append function of gzopen() can be used to create
   such a file.  (Also see gzflush() for another way to do this.)  When
   appending, gzopen does not test whether the file begins with a gzip stream,
```

```
   nor does it look for the end of the gzip streams to begin appending.  gzopen
   will simply append a gzip stream to the existing file.

     gzopen can be used to read a file which is not in gzip format; in this
   case gzread will directly read from the file without decompression.  When
   reading, this will be detected automatically by looking for the magic two-
   byte gzip header.

     gzopen returns NULL if the file could not be opened, if there was
   insufficient memory to allocate the gzFile state, or if an invalid mode was
   specified (an 'r', 'w', or 'a' was not provided, or '+' was provided).
   errno can be checked to determine if the reason gzopen failed was that the
   file could not be opened.
*/

ZEXTERN gzFile ZEXPORT gzdopen OF((int fd, const char *mode));
/*
     gzdopen associates a gzFile with the file descriptor fd.  File descriptors
   are obtained from calls like open, dup, creat, pipe or fileno (if the file
   has been previously opened with fopen).  The mode parameter is as in gzopen.

     The next call of gzclose on the returned gzFile will also close the file
   descriptor fd, just like fclose(fdopen(fd, mode)) closes the file descriptor
   fd.  If you want to keep fd open, use fd = dup(fd_keep); gz = gzdopen(fd,
   mode);.  The duplicated descriptor should be saved to avoid a leak, since
   gzdopen does not close fd if it fails.  If you are using fileno() to get the
   file descriptor from a FILE *, then you will have to use dup() to avoid
   double-close()ing the file descriptor.  Both gzclose() and fclose() will
   close the associated file descriptor, so they need to have different file
   descriptors.

     gzdopen returns NULL if there was insufficient memory to allocate the
   gzFile state, if an invalid mode was specified (an 'r', 'w', or 'a' was not
   provided, or '+' was provided), or if fd is -1.  The file descriptor is not
   used until the next gz* read, write, seek, or close operation, so gzdopen
   will not detect if fd is invalid (unless fd is -1).
*/

ZEXTERN int ZEXPORT gzbuffer OF((gzFile file, unsigned size));
/*
     Set the internal buffer size used by this library's functions.  The
   default buffer size is 8192 bytes.  This function must be called after
   gzopen() or gzdopen(), and before any other calls that read or write the
   file.  The buffer memory allocation is always deferred to the first read or
   write.  Two buffers are allocated, either both of the specified size when
   writing, or one of the specified size and the other twice that size when
   reading.  A larger buffer size of, for example, 64K or 128K bytes will
   noticeably increase the speed of decompression (reading).

     The new buffer size also affects the maximum length for gzprintf().

     gzbuffer() returns 0 on success, or -1 on failure, such as being called
   too late.
*/

ZEXTERN int ZEXPORT gzsetparams OF((gzFile file, int level, int strategy));
/*
     Dynamically update the compression level or strategy.  See the description
   of deflateInit2 for the meaning of these parameters.

     gzsetparams returns Z_OK if success, or Z_STREAM_ERROR if the file was not
   opened for writing.
*/

ZEXTERN int ZEXPORT gzread OF((gzFile file, voidp buf, unsigned len));
/*
```

```
1315      Reads the given number of uncompressed bytes from the compressed file.  If
1316    the input file is not in gzip format, gzread copies the given number of
1317    bytes into the buffer directly from the file.

1319      After reaching the end of a gzip stream in the input, gzread will continue
1320    to read, looking for another gzip stream.  Any number of gzip streams may be
1321    concatenated in the input file, and will all be decompressed by gzread().
1322    If something other than a gzip stream is encountered after a gzip stream,
1323    that remaining trailing garbage is ignored (and no error is returned).

1325      gzread can be used to read a gzip file that is being concurrently written.
1326    Upon reaching the end of the input, gzread will return with the available
1327    data.  If the error code returned by gzerror is Z_OK or Z_BUF_ERROR, then
1328    gzclearerr can be used to clear the end of file indicator in order to permit
1329    gzread to be tried again.  Z_OK indicates that a gzip stream was completed
1330    on the last gzread.  Z_BUF_ERROR indicates that the input file ended in the
1331    middle of a gzip stream.  Note that gzread does not return -1 in the event
1332    of an incomplete gzip stream.  This error is deferred until gzclose(), which
1333    will return Z_BUF_ERROR if the last gzread ended in the middle of a gzip
1334    stream.  Alternatively, gzerror can be used before gzclose to detect this
1335    case.

1337      gzread returns the number of uncompressed bytes actually read, less than
1338    len for end of file, or -1 for error.
1339 */

1346    error.
1347 */

1349 ZEXTERN int ZEXPORTVA gzprintf Z_ARG((gzFile file, const char *format, ...));
1350 /*
1351      Converts, formats, and writes the arguments to the compressed file under
1352    control of the format string, as in fprintf.  gzprintf returns the number of
1353    uncompressed bytes actually written, or 0 in case of error.  The number of
1354    uncompressed bytes written is limited to 8191, or one less than the buffer
1355    size given to gzbuffer().  The caller should assure that this limit is not
1356    exceeded.  If it is exceeded, then gzprintf() will return an error (0) with
1357    nothing written.  In this case, there may also be a buffer overflow with
1358    unpredictable consequences, which is possible only if zlib was compiled with
1359    the insecure functions sprintf() or vsprintf() because the secure snprintf()
1360    or vsnprintf() functions were not available.  This can be determined using
1361    zlibCompileFlags().
1362 */

1364 ZEXTERN int ZEXPORT gzputs OF((gzFile file, const char *s));
1365 /*
1366      Writes the given null-terminated string to the compressed file, excluding
1367    the terminating null character.

1369      gzputs returns the number of characters written, or -1 in case of error.
1370 */

1372 ZEXTERN char * ZEXPORT gzgets OF((gzFile file, char *buf, int len));
1373 /*
1374      Reads bytes from the compressed file until len-1 characters are read, or a
1375    newline character is read and transferred to buf, or an end-of-file
1376    condition is encountered.  If any characters are read or if len == 1, the
1377    string is terminated with a null character.  If no characters are read due
1378    to an end-of-file or len < 1, then the buffer is left untouched.

1380      gzgets returns buf which is a null-terminated string, or it returns NULL
```

```
1381    for end-of-file or in case of error.  If there was an error, the contents at
1382    buf are indeterminate.
1383 */

1385 ZEXTERN int ZEXPORT gzputc OF((gzFile file, int c));
1386 /*
1387      Writes c, converted to an unsigned char, into the compressed file.  gzputc
1388    returns the value that was written, or -1 in case of error.
1389 */

1391 ZEXTERN int ZEXPORT gzgetc OF((gzFile file));
1392 /*
1393      Reads one byte from the compressed file.  gzgetc returns this byte or -1
1394    in case of end of file or error.  This is implemented as a macro for speed.
1395    As such, it does not do all of the checking the other functions do.  I.e.
1396    it does not check to see if file is NULL, nor whether the structure file
1397    points to has been clobbered or not.
1398 */

1400 ZEXTERN int ZEXPORT gzungetc OF((int c, gzFile file));
1401 /*
1402      Push one character back onto the stream to be read as the first character
1403    on the next read.  At least one character of push-back is allowed.
1404    gzungetc() returns the character pushed, or -1 on failure.  gzungetc() will
1405    fail if c is -1, and may fail if a character has been pushed but not read
1406    yet.  If gzungetc is used immediately after gzopen or gzdopen, at least the
1407    output buffer size of pushed characters is allowed.  (See gzbuffer above.)
1408    The pushed character will be discarded if the stream is repositioned with
1409    gzseek() or gzrewind().
1410 */

1413 /*
1414      Flushes all pending output into the compressed file.  The parameter flush
1415    is as in the deflate() function.  The return value is the zlib error number
1416    (see function gzerror below).  gzflush is only permitted when writing.

1418      If the flush parameter is Z_FINISH, the remaining data is written and the
1419    gzip stream is completed in the output.  If gzwrite() is called again, a new
1420    gzip stream will be started in the output.  gzread() is able to read such
1421    concatented gzip streams.

1423      gzflush should be called only when strictly necessary because it will
1424    degrade compression if called too often.
1425 */

1427 /*
1428 ZEXTERN z_off_t ZEXPORT gzseek OF((gzFile file,
1429                                    z_off_t offset, int whence));

1431      Sets the starting position for the next gzread or gzwrite on the given
1432    compressed file.  The offset represents a number of bytes in the
1433    uncompressed data stream.  The whence parameter is defined as in lseek(2);
1434    the value SEEK_END is not supported.

1436      If the file is opened for reading, this function is emulated but can be
1437    extremely slow.  If the file is opened for writing, only forward seeks are
1438    supported; gzseek then compresses a sequence of zeroes up to the new
1439    starting position.

1441      gzseek returns the resulting offset location as measured in bytes from
1442    the beginning of the uncompressed stream, or -1 in case of error, in
1443    particular if the file is opened for writing and the new starting position
1444    would be before the current position.
1445 */
```

```
1447 ZEXTERN int ZEXPORT    gzrewind OF((gzFile file));
1448 /*
1449      Rewinds the given file. This function is supported only for reading.

1451      gzrewind(file) is equivalent to (int)gzseek(file, 0L, SEEK_SET)
1452 */

1454 /*
1455 ZEXTERN z_off_t ZEXPORT    gztell OF((gzFile file));

1457      Returns the starting position for the next gzread or gzwrite on the given
1458    compressed file.  This position represents a number of bytes in the
1459    uncompressed data stream, and is zero when starting, even if appending or
1460    reading a gzip stream from the middle of a file using gzdopen().

1462      gztell(file) is equivalent to gzseek(file, 0L, SEEK_CUR)
1463 */

1465 /*
1466 ZEXTERN z_off_t ZEXPORT gzoffset OF((gzFile file));

1468      Returns the current offset in the file being read or written.  This offset
1469    includes the count of bytes that precede the gzip stream, for example when
1470    appending or when using gzdopen() for reading.  When reading, the offset
1471    does not include as yet unused buffered input.  This information can be used
1472    for a progress indicator.  On error, gzoffset() returns -1.
1473 */

1475 ZEXTERN int ZEXPORT gzeof OF((gzFile file));
1476 /*
1477      Returns true (1) if the end-of-file indicator has been set while reading,
1478    false (0) otherwise.  Note that the end-of-file indicator is set only if the
1479    read tried to go past the end of the input, but came up short.  Therefore,
1480    just like feof(), gzeof() may return false even if there is no more data to
1481    read, in the event that the last read request was for the exact number of
1482    bytes remaining in the input file.  This will happen if the input file size
1483    is an exact multiple of the buffer size.

1485      If gzeof() returns true, then the read functions will return no more data,
1486    unless the end-of-file indicator is reset by gzclearerr() and the input file
1487    has grown since the previous end of file was detected.
1488 */

1490 ZEXTERN int ZEXPORT gzdirect OF((gzFile file));
1491 /*
1492      Returns true (1) if file is being copied directly while reading, or false
1493    (0) if file is a gzip stream being decompressed.

1495      If the input file is empty, gzdirect() will return true, since the input
1496    does not contain a gzip stream.

1498      If gzdirect() is used immediately after gzopen() or gzdopen() it will
1499    cause buffers to be allocated to allow reading the file to determine if it
1500    is a gzip file.  Therefore if gzbuffer() is used, it should be called before
1501    gzdirect().

1503      When writing, gzdirect() returns true (1) if transparent writing was
1504    requested ("wT" for the gzopen() mode), or false (0) otherwise.  (Note:
1505    gzdirect() is not needed when writing.  Transparent writing must be
1506    explicitly requested, so the application already knows the answer.  When
1507    linking statically, using gzdirect() will include all of the zlib code for
1508    gzip file reading and decompression, which may not be desired.)
1509 */

1511 ZEXTERN int ZEXPORT    gzclose OF((gzFile file));

```

```
1513      Flushes all pending output if necessary, closes the compressed file and
1514    deallocates the (de)compression state.  Note that once file is closed, you
1515    cannot call gzerror with file, since its structures have been deallocated.
1516    gzclose must not be called more than once on the same file, just as free
1517    must not be called more than once on the same allocation.

1519      gzclose will return Z_STREAM_ERROR if file is not valid, Z_ERRNO on a
1520    file operation error, Z_MEM_ERROR if out of memory, Z_BUF_ERROR if the
1521    last read ended in the middle of a gzip stream, or Z_OK on success.
1522 */

1524 ZEXTERN int ZEXPORT gzclose_r OF((gzFile file));
1525 ZEXTERN int ZEXPORT gzclose_w OF((gzFile file));
1526 /*
1527      Same as gzclose(), but gzclose_r() is only for use when reading, and
1528    gzclose_w() is only for use when writing or appending.  The advantage to
1529    using these instead of gzclose() is that they avoid linking in zlib
1530    compression or decompression code that is not used when only reading or only
1531    writing respectively.  If gzclose() is used, then both compression and
1532    decompression code will be included the application when linking to a static
1533    zlib library.
1534 */

1536 ZEXTERN const char * ZEXPORT gzerror OF((gzFile file, int *errnum));
1537 /*
1538      Returns the error message for the last error which occurred on the given
1539    compressed file.  errnum is set to zlib error number.  If an error occurred
1540    in the file system and not in the compression library, errnum is set to
1541    Z_ERRNO and the application may consult errno to get the exact error code.

1543      The application must not modify the returned string.  Future calls to
1544    this function may invalidate the previously returned string.  If file is
1545    closed, then the string previously returned by gzerror will no longer be
1546    available.

1548      gzerror() should be used to distinguish errors from end-of-file for those
1549    functions above that do not distinguish those cases in their return values.
1550 */

1552 ZEXTERN void ZEXPORT gzclearerr OF((gzFile file));
1553 /*
1554      Clears the error and end-of-file flags for file.  This is analogous to the
1555    clearerr() function in stdio.  This is useful for continuing to read a gzip
1556    file that is being written concurrently.
1557 */

1559 #endif /* !Z_SOLO */

1561                         /* checksum functions */

1563 /*
1564      These functions are not related to compression but are exported
1565    anyway because they might be useful in applications using the compression
1566    library.
1567 */

1569 ZEXTERN uLong ZEXPORT adler32 OF((uLong adler, const Bytef *buf, uInt len));
1570 /*
1571      Update a running Adler-32 checksum with the bytes buf[0..len-1] and
1572    return the updated checksum.  If buf is Z_NULL, this function returns the
1573    required initial value for the checksum.

1575      An Adler-32 checksum is almost as reliable as a CRC32 but can be computed
1576    much faster.

1578    Usage example:
```

```
1580      uLong adler = adler32(0L, Z_NULL, 0);

1582      while (read_buffer(buffer, length) != EOF) {
1583        adler = adler32(adler, buffer, length);
1584      }
1585      if (adler != original_adler) error();
1586 */

1588 /*
1589 ZEXTERN uLong ZEXPORT adler32_combine OF((uLong adler1, uLong adler2,
1590                                           z_off_t len2));

1592      Combine two Adler-32 checksums into one.  For two sequences of bytes, seq1
1593    and seq2 with lengths len1 and len2, Adler-32 checksums were calculated for
1594    each, adler1 and adler2.  adler32_combine() returns the Adler-32 checksum of
1595    seq1 and seq2 concatenated, requiring only adler1, adler2, and len2.  Note
1596    that the z_off_t type (like off_t) is a signed integer.  If len2 is
1597    negative, the result has no meaning or utility.
1598 */

1600 ZEXTERN uLong ZEXPORT crc32   OF((uLong crc, const Bytef *buf, uInt len));
1601 /*
1602      Update a running CRC-32 with the bytes buf[0..len-1] and return the
1603    updated CRC-32.  If buf is Z_NULL, this function returns the required
1604    initial value for the crc.  Pre- and post-conditioning (one's complement) is
1605    performed within this function so it shouldn't be done by the application.

1607    Usage example:

1609      uLong crc = crc32(0L, Z_NULL, 0);

1611      while (read_buffer(buffer, length) != EOF) {
1612        crc = crc32(crc, buffer, length);
1613      }
1614      if (crc != original_crc) error();
1615 */

1617 /*
1618 ZEXTERN uLong ZEXPORT crc32_combine OF((uLong crc1, uLong crc2, z_off_t len2));

1620      Combine two CRC-32 check values into one.  For two sequences of bytes,
1621    seq1 and seq2 with lengths len1 and len2, CRC-32 check values were
1622    calculated for each, crc1 and crc2.  crc32_combine() returns the CRC-32
1623    check value of seq1 and seq2 concatenated, requiring only crc1, crc2, and
1624    len2.
1625 */

/*
    The 'zlib' compression library provides in-memory compression and
  decompression functions, including integrity checks of the uncompressed data.
  This version of the library supports only one compression method (deflation)
  but other algorithms will be added later and will have the same stream
  interface.

    Compression can be done in a single step if the buffers are large enough,
  or can be done by repeated calls of the compression function.  In the latter
  case, the application must provide more input and/or consume the output
  (providing more output space) before each call.

    The compressed data format used by default by the in-memory functions is
  the zlib format, which is a zlib wrapper documented in RFC 1950, wrapped
```

```
  around a deflate stream, which is itself documented in RFC 1951.

    The library also supports reading and writing files in gzip (.gz) format
  with an interface similar to that of stdio using the functions that start
  with "gz".  The gzip format is different from the zlib format.  gzip is a
  gzip wrapper, documented in RFC 1952, wrapped around a deflate stream.

    This library can optionally read and write gzip streams in memory as well.

    The zlib format was designed to be compact and fast for use in memory
  and on communications channels.  The gzip format was designed for single-
  file compression on file systems, has a larger header than zlib to maintain
  directory information, and uses a different, slower check method than zlib.

    The library does not install any signal handler.  The decoder checks
  the consistency of the compressed data, so the library should never crash
  even in case of corrupted input.

} gz_header;

typedef gz_header FAR *gz_headerp;

/*
     The application must update next_in and avail_in when avail_in has dropped
   to zero.  It must update next_out and avail_out when avail_out has dropped
   to zero.  The application must initialize zalloc, zfree and opaque before
   calling the init function.  All other fields are set by the compression
   library and must not be updated by the application.

     The opaque value provided by the application will be passed as the first
   parameter for calls of zalloc and zfree.  This can be useful for custom
   memory management.  The compression library attaches no meaning to the
   opaque value.

     zalloc must return Z_NULL if there is not enough memory for the object.
   If zlib is used in a multi-threaded application, zalloc and zfree must be
   thread safe.

     On 16-bit systems, the functions zalloc and zfree must be able to allocate
   exactly 65536 bytes, but will not be required to allocate more than this if
   the symbol MAXSEG_64K is defined (see zconf.h).  WARNING: On MSDOS, pointers
   returned by zalloc for objects of exactly 65536 bytes *must* have their
   offset normalized to zero.  The default allocation function provided by this
   library ensures this (see zutil.c).  To reduce memory requirements and avoid
   any allocation of 64K objects, at the expense of compression ratio, compile
   the library with -DMAX_WBITS=14 (see zconf.h).

     The fields total_in and total_out can be used for statistics or progress
   reports.  After compression, total_in holds the total size of the
   uncompressed data and may be saved for use in the decompressor (particularly
   if the decompressor wants to decompress everything in a single step).

   is automatically made by deflateInit and inflateInit.
 */

/*
ZEXTERN int ZEXPORT deflateInit OF((z_streamp strm, int level));

     Initializes the internal stream state for compression.  The fields
   zalloc, zfree and opaque must be initialized before by the caller.  If
   zalloc and zfree are set to Z_NULL, deflateInit updates them to use default
   allocation functions.

     The compression level must be Z_DEFAULT_COMPRESSION, or between 0 and 9:
   1 gives best speed, 9 gives best compression, 0 gives no compression at all
   (the input data is simply copied a block at a time).  Z_DEFAULT_COMPRESSION
   requests a default compromise between speed and compression (currently
   equivalent to level 6).

     deflateInit returns Z_OK if success, Z_MEM_ERROR if there was not enough
   memory, Z_STREAM_ERROR if level is not a valid compression level, or
   Z_VERSION_ERROR if the zlib library version (zlib_version) is incompatible
   with the version assumed by the caller (ZLIB_VERSION).  msg is set to null
   if there is no error message.  deflateInit does not perform any compression:
   this will be done by deflate().
*/

ZEXTERN int ZEXPORT deflate OF((z_streamp strm, int flush));
/*
    deflate compresses as much data as possible, and stops when the input
  buffer becomes empty or the output buffer becomes full.  It may introduce
  some output latency (reading input without producing any output) except when
  forced to flush.

    The detailed semantics are as follows.  deflate performs one or both of the
  following actions:

  - Compress more input starting at next_in and update next_in and avail_in
    accordingly.  If not all input can be processed (because there is not
    enough room in the output buffer), next_in and avail_in are updated and
```

```
   processing will resume at this point for the next call of deflate().

- Provide more output starting at next_out and update next_out and avail_out
   accordingly.  This action is forced if the parameter flush is non zero.
   Forcing flush frequently degrades the compression ratio, so this parameter
   should be set only when necessary (in interactive applications).  Some
   output may be provided even if flush is not set.

   Before the call of deflate(), the application should ensure that at least
one of the actions is possible, by providing more input and/or consuming more
output, and updating avail_in or avail_out accordingly; avail_out should
never be zero before the call.  The application can consume the compressed
output when it wants, for example when the output buffer is full (avail_out
== 0), or after each call of deflate().  If deflate returns Z_OK and with
zero avail_out, it must be called again after making room in the output
buffer because there might be more output pending.

   Normally the parameter flush is set to Z_NO_FLUSH, which allows deflate to
decide how much data to accumulate before producing output, in order to
maximize compression.

   If the parameter flush is set to Z_SYNC_FLUSH, all pending output is
flushed to the output buffer and the output is aligned on a byte boundary, so
that the decompressor can get all input data available so far.  (In
particular avail_in is zero after the call if enough output space has been
provided before the call.) Flushing may degrade compression for some
compression algorithms and so it should be used only when necessary.  This
completes the current deflate block and follows it with an empty stored block
that is three bits plus filler bits to the next byte, followed by four bytes
(00 00 ff ff).

   If flush is set to Z_PARTIAL_FLUSH, all pending output is flushed to the
output buffer, but the output is not aligned to a byte boundary.  All of the
input data so far will be available to the decompressor, as for Z_SYNC_FLUSH.
This completes the current deflate block and follows it with an empty fixed
codes block that is 10 bits long.  This assures that enough bytes are output
in order for the decompressor to finish the block before the empty fixed code
block.

   If flush is set to Z_BLOCK, a deflate block is completed and emitted, as
for Z_SYNC_FLUSH, but the output is not aligned on a byte boundary, and up to
seven bits of the current block are held to be written as the next byte after
the next deflate block is completed.  In this case, the decompressor may not
be provided enough bits at this point in order to complete decompression of
the data provided so far to the compressor.  It may need to wait for the next
block to be emitted.  This is for advanced applications that need to control
the emission of deflate blocks.

   If flush is set to Z_FULL_FLUSH, all output is flushed as with
Z_SYNC_FLUSH, and the compression state is reset so that decompression can
restart from this point if previous compressed data has been damaged or if
random access is desired.  Using Z_FULL_FLUSH too often can seriously degrade
compression.

   If deflate returns with avail_out == 0, this function must be called again
with the same value of the flush parameter and more output space (updated
avail_out), until the flush is complete (deflate returns with non-zero
avail_out).  In the case of a Z_FULL_FLUSH or Z_SYNC_FLUSH, make sure that
avail_out is greater than six to avoid repeated flush markers due to
avail_out == 0 on return.

   If the parameter flush is set to Z_FINISH, pending input is processed,
pending output is flushed and deflate returns with Z_STREAM_END if there was
enough output space; if deflate returns with Z_OK, this function must be
called again with Z_FINISH and more output space (updated avail_out) but no
more input data, until it returns with Z_STREAM_END or an error.  After
```

```
   deflate has returned Z_STREAM_END, the only possible operations on the stream
   are deflateReset or deflateEnd.

     Z_FINISH can be used immediately after deflateInit if all the compression
   is to be done in a single step.  In this case, avail_out must be at least the
   value returned by deflateBound (see below).  Then deflate is guaranteed to
   return Z_STREAM_END.  If not enough output space is provided, deflate will
   not return Z_STREAM_END, and it must be called again as described above.

     deflate() sets strm->adler to the adler32 checksum of all input read
   so far (that is, total_in bytes).

     deflate() may update strm->data_type if it can make a good guess about
   the input data type (Z_BINARY or Z_TEXT).  In doubt, the data is considered
   binary.  This field is only for information purposes and does not affect the
   compression algorithm in any manner.

     deflate() returns Z_OK if some progress has been made (more input
   processed or more output produced), Z_STREAM_END if all input has been
   consumed and all output has been produced (only when flush is set to
   Z_FINISH), Z_STREAM_ERROR if the stream state was inconsistent (for example
   if next_in or next_out was Z_NULL), Z_BUF_ERROR if no progress is possible
   (for example avail_in or avail_out was zero).  Note that Z_BUF_ERROR is not
   fatal, and deflate() can be called again with more input and more output
   space to continue compressing.
*/

ZEXTERN int ZEXPORT deflateEnd OF((z_streamp strm));
/*
     All dynamically allocated data structures for this stream are freed.
    This function discards any unprocessed input and does not flush any pending
    output.

     deflateEnd returns Z_OK if success, Z_STREAM_ERROR if the
    stream state was inconsistent, Z_DATA_ERROR if the stream was freed
    prematurely (some input or output was discarded).  In the error case, msg
    may be set but then points to a static string (which must not be
    deallocated).
*/

/*
ZEXTERN int ZEXPORT inflateInit OF((z_streamp strm));

     Initializes the internal stream state for decompression.  The fields
    next_in, avail_in, zalloc, zfree and opaque must be initialized before by
    the caller.  If next_in is not Z_NULL and avail_in is large enough (the
    exact value depends on the compression method), inflateInit determines the
    compression method from the zlib header and allocates all data structures
    accordingly; otherwise the allocation will be deferred to the first call of
    inflate.  If zalloc and zfree are set to Z_NULL, inflateInit updates them to
    use default allocation functions.

     inflateInit returns Z_OK if success, Z_MEM_ERROR if there was not enough
    memory, Z_VERSION_ERROR if the zlib library version is incompatible with the
    version assumed by the caller, or Z_STREAM_ERROR if the parameters are
    invalid, such as a null pointer to the structure.  msg is set to null if
    there is no error message.  inflateInit does not perform any decompression
    apart from possibly reading the zlib header if present: actual decompression
    will be done by inflate().  (So next_in and avail_in may be modified, but
    next_out and avail_out are unused and unchanged.) The current implementation
    of inflateInit() does not process any header information -- that is deferred
    until inflate() is called.
*/
```

```
ZEXTERN int ZEXPORT inflate OF((z_streamp strm, int flush));
/*
    inflate decompresses as much data as possible, and stops when the input
  buffer becomes empty or the output buffer becomes full.  It may introduce
  some output latency (reading input without producing any output) except when
  forced to flush.

  The detailed semantics are as follows.  inflate performs one or both of the
  following actions:

  - Decompress more input starting at next_in and update next_in and avail_in
    accordingly.  If not all input can be processed (because there is not
    enough room in the output buffer), next_in is updated and processing will
    resume at this point for the next call of inflate().

  - Provide more output starting at next_out and update next_out and avail_out
    accordingly.  inflate() provides as much output as possible, until there is
    no more input data or no more space in the output buffer (see below about
    the flush parameter).

    Before the call of inflate(), the application should ensure that at least
  one of the actions is possible, by providing more input and/or consuming more
  output, and updating the next_* and avail_* values accordingly.  The
  application can consume the uncompressed output when it wants, for example
  when the output buffer is full (avail_out == 0), or after each call of
  inflate().  If inflate returns Z_OK and with zero avail_out, it must be
  called again after making room in the output buffer because there might be
  more output pending.

    The flush parameter of inflate() can be Z_NO_FLUSH, Z_SYNC_FLUSH, Z_FINISH,
  Z_BLOCK, or Z_TREES.  Z_SYNC_FLUSH requests that inflate() flush as much
  output as possible to the output buffer.  Z_BLOCK requests that inflate()
  stop if and when it gets to the next deflate block boundary.  When decoding
  the zlib or gzip format, this will cause inflate() to return immediately
  after the header and before the first block.  When doing a raw inflate,
  inflate() will go ahead and process the first block, and will return when it
  gets to the end of that block, or when it runs out of data.

    The Z_BLOCK option assists in appending to or combining deflate streams.
  Also to assist in this, on return inflate() will set strm->data_type to the
  number of unused bits in the last byte taken from strm->next_in, plus 64 if
  inflate() is currently decoding the last block in the deflate stream, plus
  128 if inflate() returned immediately after decoding an end-of-block code or
  decoding the complete header up to just before the first byte of the deflate
  stream.  The end-of-block will not be indicated until all of the uncompressed
  data from that block has been written to strm->next_out.  The number of
  unused bits may in general be greater than seven, except when bit 7 of
  data_type is set, in which case the number of unused bits will be less than
  eight.  data_type is set as noted here every time inflate() returns for all
  flush options, and so can be used to determine the amount of currently
  consumed input in bits.

    The Z_TREES option behaves as Z_BLOCK does, but it also returns when the
  end of each deflate block header is reached, before any actual data in that
  block is decoded.  This allows the caller to determine the length of the
  deflate block header for later use in random access within a deflate block.
  256 is added to the value of strm->data_type when inflate() returns
  immediately after reaching the end of the deflate block header.

    inflate() should normally be called until it returns Z_STREAM_END or an
  error.  However if all decompression is to be performed in a single step (a
  single call of inflate), the parameter flush should be set to Z_FINISH.  In
  this case all pending input is processed and all pending output is flushed;
  avail_out must be large enough to hold all of the uncompressed data for the
  operation to complete.  (The size of the uncompressed data may have been
```

```
  saved by the compressor for this purpose.) The use of Z_FINISH is not
  required to perform an inflation in one step.  However it may be used to
  inform inflate that a faster approach can be used for the single inflate()
  call.  Z_FINISH also informs inflate to not maintain a sliding window if the
  stream completes, which reduces inflate's memory footprint.  If the stream
  does not complete, either because not all of the stream is provided or not
  enough output space is provided, then a sliding window will be allocated and
  inflate() can be called again to continue the operation as if Z_NO_FLUSH had
  been used.

     In this implementation, inflate() always flushes as much output as
  possible to the output buffer, and always uses the faster approach on the
  first call.  So the effects of the flush parameter in this implementation are
  on the return value of inflate() as noted below, when inflate() returns early
  when Z_BLOCK or Z_TREES is used, and when inflate() avoids the allocation of
  memory for a sliding window when Z_FINISH is used.

     If a preset dictionary is needed after this call (see inflateSetDictionary
  below), inflate sets strm->adler to the Adler-32 checksum of the dictionary
  chosen by the compressor and returns Z_NEED_DICT; otherwise it sets
  strm->adler to the Adler-32 checksum of all output produced so far (that is,
  total_out bytes) and returns Z_OK, Z_STREAM_END or an error code as described
  below.  At the end of the stream, inflate() checks that its computed adler32
  checksum is equal to that saved by the compressor and returns Z_STREAM_END
  only if the checksum is correct.

    inflate() can decompress and check either zlib-wrapped or gzip-wrapped
  deflate data.  The header type is detected automatically, if requested when
  initializing with inflateInit2().  Any information contained in the gzip
  header is not retained, so applications that need that information should
  instead use raw inflate, see inflateInit2() below, or inflateBack() and
  perform their own processing of the gzip header and trailer.  When processing
  gzip-wrapped deflate data, strm->adler32 is set to the CRC-32 of the output
  producted so far.  The CRC-32 is checked against the gzip trailer.

    inflate() returns Z_OK if some progress has been made (more input processed
  or more output produced), Z_STREAM_END if the end of the compressed data has
  been reached and all uncompressed output has been produced, Z_NEED_DICT if a
  preset dictionary is needed at this point, Z_DATA_ERROR if the input data was
  corrupted (input stream not conforming to the zlib format or incorrect check
  value), Z_STREAM_ERROR if the stream structure was inconsistent (for example
  next_in or next_out was Z_NULL), Z_MEM_ERROR if there was not enough memory,
  Z_BUF_ERROR if no progress is possible or if there was not enough room in the
  output buffer when Z_FINISH is used.  Note that Z_BUF_ERROR is not fatal, and
  inflate() can be called again with more input and more output space to
  continue decompressing.  If Z_DATA_ERROR is returned, the application may
  then call inflateSync() to look for a good compression block if a partial
  recovery of the data is desired.
*/

ZEXTERN int ZEXPORT inflateEnd OF((z_streamp strm));
/*
     All dynamically allocated data structures for this stream are freed.
   This function discards any unprocessed input and does not flush any pending
   output.

     inflateEnd returns Z_OK if success, Z_STREAM_ERROR if the stream state
   was inconsistent.  In the error case, msg may be set but then points to a
   static string (which must not be deallocated).

530                                      int  windowBits,
531                                      int  memLevel,
532                                      int  strategy));
533
534     This is another version of deflateInit with more compression options.  The
535   fields next_in, zalloc, zfree and opaque must be initialized before by the
536   caller.
537
538     The method parameter is the compression method.  It must be Z_DEFLATED in
539   this version of the library.
540
541     The windowBits parameter is the base two logarithm of the window size
542   (the size of the history buffer).  It should be in the range 8..15 for this
543   version of the library.  Larger values of this parameter result in better
544   compression at the expense of memory usage.  The default value is 15 if
545   deflateInit is used instead.
546
547     windowBits can also be -8..-15 for raw deflate.  In this case, -windowBits
548   determines the window size.  deflate() will then generate raw deflate data
549   with no zlib header or trailer, and will not compute an adler32 check value.
550
551     windowBits can also be greater than 15 for optional gzip encoding.  Add
552   16 to windowBits to write a simple gzip header and trailer around the
553   compressed data instead of a zlib wrapper.  The gzip header will have no
554   file name, no extra data, no comment, no modification time (set to zero), no
555   header crc, and the operating system will be set to 255 (unknown).  If a
556   gzip stream is being written, strm->adler is a crc32 instead of an adler32.
557
558     The memLevel parameter specifies how much memory should be allocated
559   for the internal compression state.  memLevel=1 uses minimum memory but is
560   slow and reduces compression ratio; memLevel=9 uses maximum memory for
561   optimal speed.  The default value is 8.  See zconf.h for total memory usage
562   as a function of windowBits and memLevel.
563
564     The strategy parameter is used to tune the compression algorithm.  Use the
565   value Z_DEFAULT_STRATEGY for normal data, Z_FILTERED for data produced by a
566   filter (or predictor), Z_HUFFMAN_ONLY to force Huffman encoding only (no
567   string match), or Z_RLE to limit match distances to one (run-length
568   encoding).  Filtered data consists mostly of small values with a somewhat
569   random distribution.  In this case, the compression algorithm is tuned to
570   compress them better.  The effect of Z_FILTERED is to force more Huffman
571   coding and less string matching; it is somewhat intermediate between
572   Z_DEFAULT_STRATEGY and Z_HUFFMAN_ONLY.  Z_RLE is designed to be almost as
573   fast as Z_HUFFMAN_ONLY, but give better compression for PNG image data.  The
574   strategy parameter only affects the compression ratio but not the
575   correctness of the compressed output even if it is not set appropriately.
576   Z_FIXED prevents the use of dynamic Huffman codes, allowing for a simpler
577   decoder for special applications.
578
579     deflateInit2 returns Z_OK if success, Z_MEM_ERROR if there was not enough
580   memory, Z_STREAM_ERROR if any parameter is invalid (such as an invalid
581   method), or Z_VERSION_ERROR if the zlib library version (zlib_version) is
582   incompatible with the version assumed by the caller (ZLIB_VERSION).  msg is
583   set to null if there is no error message.  deflateInit2 does not perform any
584   compression: this will be done by deflate().
585 */
586
587 ZEXTERN int ZEXPORT deflateSetDictionary OF((z_streamp strm,
588                                              const Bytef *dictionary,
```

```
589                                              uInt  dictLength));
590 /*
591     Initializes the compression dictionary from the given byte sequence
592   without producing any compressed output.  When using the zlib format, this
593   function must be called immediately after deflateInit, deflateInit2 or
594   deflateReset, and before any call of deflate.  When doing raw deflate, this
595   function must be called either before any call of deflate, or immediately
596   after the completion of a deflate block, i.e. after all input has been
597   consumed and all output has been delivered when using any of the flush
598   options Z_BLOCK, Z_PARTIAL_FLUSH, Z_SYNC_FLUSH, or Z_FULL_FLUSH.  The
599   compressor and decompressor must use exactly the same dictionary (see
600   inflateSetDictionary).
601
602     The dictionary should consist of strings (byte sequences) that are likely
603   to be encountered later in the data to be compressed, with the most commonly
604   used strings preferably put towards the end of the dictionary.  Using a
605   dictionary is most useful when the data to be compressed is short and can be
606   predicted with good accuracy; the data can then be compressed better than
607   with the default empty dictionary.
608
609     Depending on the size of the compression data structures selected by
610   deflateInit or deflateInit2, a part of the dictionary may in effect be
611   discarded, for example if the dictionary is larger than the window size
612   provided in deflateInit or deflateInit2.  Thus the strings most likely to be
613   useful should be put at the end of the dictionary, not at the front.  In
614   addition, the current implementation of deflate will use at most the window
615   size minus 262 bytes of the provided dictionary.
616
617     Upon return of this function, strm->adler is set to the adler32 value
618   of the dictionary; the decompressor may later use this value to determine
619   which dictionary has been used by the compressor.  (The adler32 value
620   applies to the whole dictionary even if only a subset of the dictionary is
621   actually used by the compressor.) If a raw deflate was requested, then the
622   adler32 value is not computed and strm->adler is not set.
623
624     deflateSetDictionary returns Z_OK if success, or Z_STREAM_ERROR if a
625   parameter is invalid (e.g.  dictionary being Z_NULL) or the stream state is
626   inconsistent (for example if deflate has already been called for this stream
627   or if not at a block boundary for raw deflate).  deflateSetDictionary does
628   not perform any compression: this will be done by deflate().
629 */
630
631 ZEXTERN int ZEXPORT deflateCopy OF((z_streamp dest,
632                                     z_streamp source));
633 /*
634     Sets the destination stream as a complete copy of the source stream.
635
636     This function can be useful when several compression strategies will be
637   tried, for example when there are several ways of pre-processing the input
638   data with a filter.  The streams that will be discarded should then be freed
639   by calling deflateEnd.  Note that deflateCopy duplicates the internal
640   compression state which can be quite large, so this strategy is slow and can
641   consume lots of memory.
642
643     deflateCopy returns Z_OK if success, Z_MEM_ERROR if there was not
644   enough memory, Z_STREAM_ERROR if the source stream state was inconsistent
645   (such as zalloc being Z_NULL).  msg is left unchanged in both source and
646   destination.
647 */
648
649 ZEXTERN int ZEXPORT deflateReset OF((z_streamp strm));
650 /*
651     This function is equivalent to deflateEnd followed by deflateInit,
652   but does not free and reallocate all the internal compression state.  The
653   stream will keep the same compression level and any other attributes that
654   may have been set by deflateInit2.
```

```
656      deflateReset returns Z_OK if success, or Z_STREAM_ERROR if the source
657    stream state was inconsistent (such as zalloc or state being Z_NULL).
658 */
659
660 ZEXTERN int ZEXPORT deflateParams OF((z_streamp strm,
661                                       int level,
662                                       int strategy));
663 /*
664      Dynamically update the compression level and compression strategy.  The
665    interpretation of level and strategy is as in deflateInit2.  This can be
666    used to switch between compression and straight copy of the input data, or
667    to switch to a different kind of input data requiring a different strategy.
668    If the compression level is changed, the input available so far is
669    compressed with the old level (and may be flushed); the new level will take
670    effect only at the next call of deflate().
671
672      Before the call of deflateParams, the stream state must be set as for
673    a call of deflate(), since the currently available input may have to be
674    compressed and flushed.  In particular, strm->avail_out must be non-zero.
675
676      deflateParams returns Z_OK if success, Z_STREAM_ERROR if the source
677    stream state was inconsistent or if a parameter was invalid, Z_BUF_ERROR if
678    strm->avail_out was zero.
679 */

714                                        unsigned *pending,
715                                        int *bits));
716 /*
717      deflatePending() returns the number of bytes and bits of output that have
718    been generated, but not yet provided in the available output.  The bytes not
719    provided would be due to the available output space having being consumed.
720    The number of bits of output not provided are between 0 and 7, where they
```

```
721    await more bits to join them in order to fill out a full byte.  If pending
722    or bits are Z_NULL, then those values are not set.
723
724      deflatePending returns Z_OK if success, or Z_STREAM_ERROR if the source
725    stream state was inconsistent.
726  */
727
728 ZEXTERN int ZEXPORT deflatePrime OF((z_streamp strm,
729                                      int bits,
730                                      int value));
731 /*
732      deflatePrime() inserts bits in the deflate output stream.  The intent
733    is that this function is used to start off the deflate output with the bits
734    leftover from a previous deflate stream when appending to it.  As such, this
735    function can only be used for raw deflate, and must be used before the first
736    deflate() call after a deflateInit2() or deflateReset().  bits must be less
737    than or equal to 16, and that many of the least significant bits of value
738    will be inserted in the output.
739
740      deflatePrime returns Z_OK if success, Z_BUF_ERROR if there was not enough
741    room in the internal buffer to insert the bits, or Z_STREAM_ERROR if the
742    source stream state was inconsistent.
743 */
744
745 ZEXTERN int ZEXPORT deflateSetHeader OF((z_streamp strm,
746                                          gz_headerp head));
747 /*
748      deflateSetHeader() provides gzip header information for when a gzip
749    stream is requested by deflateInit2().  deflateSetHeader() may be called
750    after deflateInit2() or deflateReset() and before the first call of
751    deflate().  The text, time, os, extra field, name, and comment information
752    in the provided gz_header structure are written to the gzip header (xflag is
753    ignored -- the extra flags are set according to the compression level).  The
754    caller must assure that, if not Z_NULL, name and comment are terminated with
755    a zero byte, and that if extra is not Z_NULL, that extra_len bytes are
756    available there.  If hcrc is true, a gzip header crc is included.  Note that
757    the current versions of the command-line version of gzip (up through version
758    1.3.x) do not support header crc's, and will report that it is a "multi-part
759    gzip file" and give up.
760
761      If deflateSetHeader is not used, the default gzip header has text false,
762    the time set to zero, and os set to 255, with no extra, name, or comment
763    fields.  The gzip header is returned to the default state by deflateReset().
764
765      deflateSetHeader returns Z_OK if success, or Z_STREAM_ERROR if the source
766    stream state was inconsistent.
767 */
768
769 /*
770 ZEXTERN int ZEXPORT inflateInit2 OF((z_streamp strm,
771                                      int  windowBits));
772
773      This is another version of inflateInit with an extra parameter.  The
774    fields next_in, avail_in, zalloc, zfree and opaque must be initialized
775    before by the caller.
776
777      The windowBits parameter is the base two logarithm of the maximum window
778    size (the size of the history buffer).  It should be in the range 8..15 for
779    this version of the library.  The default value is 15 if inflateInit is used
780    instead.  windowBits must be greater than or equal to the windowBits value
781    provided to deflateInit2() while compressing, or it must be equal to 15 if
782    deflateInit2() was not used.  If a compressed stream with a larger window
783    size is given as input, inflate() will return with the error code
784    Z_DATA_ERROR instead of trying to allocate a larger window.
785
786      windowBits can also be zero to request that inflate use the window size in
```

```
787    the zlib header of the compressed stream.
788
789      windowBits can also be -8..-15 for raw inflate.  In this case, -windowBits
790    determines the window size.  inflate() will then process raw deflate data,
791    not looking for a zlib or gzip header, not generating a check value, and not
792    looking for any check values for comparison at the end of the stream.  This
793    is for use with other formats that use the deflate compressed data format
794    such as zip.  Those formats provide their own check values.  If a custom
795    format is developed using the raw deflate format for compressed data, it is
796    recommended that a check value such as an adler32 or a crc32 be applied to
797    the uncompressed data as is done in the zlib, gzip, and zip formats.  For
798    most applications, the zlib format should be used as is.  Note that comments
799    above on the use in deflateInit2() applies to the magnitude of windowBits.
800
801      windowBits can also be greater than 15 for optional gzip decoding.  Add
802    32 to windowBits to enable zlib and gzip decoding with automatic header
803    detection, or add 16 to decode only the gzip format (the zlib format will
804    return a Z_DATA_ERROR).  If a gzip stream is being decoded, strm->adler is a
805    crc32 instead of an adler32.
806
807      inflateInit2 returns Z_OK if success, Z_MEM_ERROR if there was not enough
808    memory, Z_VERSION_ERROR if the zlib library version is incompatible with the
809    version assumed by the caller, or Z_STREAM_ERROR if the parameters are
810    invalid, such as a null pointer to the structure.  msg is set to null if
811    there is no error message.  inflateInit2 does not perform any decompression
812    apart from possibly reading the zlib header if present: actual decompression
813    will be done by inflate().  (So next_in and avail_in may be modified, but
814    next_out and avail_out are unused and unchanged.) The current implementation
815    of inflateInit2() does not process any header information -- that is
816    deferred until inflate() is called.
817 */

819 ZEXTERN int ZEXPORT inflateSetDictionary OF((z_streamp strm,
820                                              const Bytef *dictionary,
821                                              uInt  dictLength));
822 /*
823      Initializes the decompression dictionary from the given uncompressed byte
824    sequence.  This function must be called immediately after a call of inflate,
825    if that call returned Z_NEED_DICT.  The dictionary chosen by the compressor
826    can be determined from the adler32 value returned by that call of inflate.
827    The compressor and decompressor must use exactly the same dictionary (see
828    deflateSetDictionary).  For raw inflate, this function can be called at any
829    time to set the dictionary.  If the provided dictionary is smaller than the
830    window and there is already data in the window, then the provided dictionary
831    will amend what's there.  The application must insure that the dictionary
832    that was used for compression is provided.
833
834      inflateSetDictionary returns Z_OK if success, Z_STREAM_ERROR if a
835    parameter is invalid (e.g.  dictionary being Z_NULL) or the stream state is
836    inconsistent, Z_DATA_ERROR if the given dictionary doesn't match the
837    expected one (incorrect adler32 value).  inflateSetDictionary does not
838    perform any decompression: this will be done by subsequent calls of
839    inflate().
840 */
841
842 ZEXTERN int ZEXPORT inflateGetDictionary OF((z_streamp strm,
843                                              Bytef *dictionary,
844                                              uInt  *dictLength));
845 /*
846      Returns the sliding dictionary being maintained by inflate.  dictLength is
847    set to the number of bytes in the dictionary, and that many bytes are copied
848    to dictionary.  dictionary must have enough space, where 32768 bytes is
849    always enough.  If inflateGetDictionary() is called with dictionary equal to
850    Z_NULL, then only the dictionary length is returned, and nothing is copied.
851    Similary, if dictLength is Z_NULL, then it is not set.
```

```
853      inflateGetDictionary returns Z_OK on success, or Z_STREAM_ERROR if the
854    stream state is inconsistent.

903                                       int windowBits));
904 /*
905      This function is the same as inflateReset, but it also permits changing
906    the wrap and window size requests.  The windowBits parameter is interpreted
907    the same as it is for inflateInit2.
908
909      inflateReset2 returns Z_OK if success, or Z_STREAM_ERROR if the source
910    stream state was inconsistent (such as zalloc or state being Z_NULL), or if
911    the windowBits parameter is invalid.
912 */
913
914 ZEXTERN int ZEXPORT inflatePrime OF((z_streamp strm,
915                                      int bits,
916                                      int value));
917 /*
918      This function inserts bits in the inflate input stream.  The intent is
```

```
   that this function is used to start inflating at a bit position in the
   middle of a byte.  The provided bits will be used before any bytes are used
   from next_in.  This function should only be used with raw inflate, and
   should be used before the first inflate() call after inflateInit2() or
   inflateReset().  bits must be less than or equal to 16, and that many of the
   least significant bits of value will be inserted in the input.

     If bits is negative, then the input stream bit buffer is emptied.  Then
   inflatePrime() can be called again to put bits in the buffer.  This is used
   to clear out bits leftover after feeding inflate a block description prior
   to feeding inflate codes.

     inflatePrime returns Z_OK if success, or Z_STREAM_ERROR if the source
   stream state was inconsistent.
*/

ZEXTERN long ZEXPORT inflateMark OF((z_streamp strm));
/*
     This function returns two values, one in the lower 16 bits of the return
   value, and the other in the remaining upper bits, obtained by shifting the
   return value down 16 bits.  If the upper value is -1 and the lower value is
   zero, then inflate() is currently decoding information outside of a block.
   If the upper value is -1 and the lower value is non-zero, then inflate is in
   the middle of a stored block, with the lower value equaling the number of
   bytes from the input remaining to copy.  If the upper value is not -1, then
   it is the number of bits back from the current bit position in the input of
   the code (literal or length/distance pair) currently being processed.  In
   that case the lower value is the number of bytes already emitted for that
   code.

     A code is being processed if inflate is waiting for more input to complete
   decoding of the code, or if it has completed decoding but is waiting for
   more output space to write the literal or match data.

     inflateMark() is used to mark locations in the input data for random
   access, which may be at bit positions, and to note those cases where the
   output of a code may span boundaries of random access blocks.  The current
   location in the input stream can be determined from avail_in and data_type
   as noted in the description for the Z_BLOCK flush parameter for inflate.

     inflateMark returns the value noted above or -1 << 16 if the provided
   source stream state was inconsistent.
*/

ZEXTERN int ZEXPORT inflateGetHeader OF((z_streamp strm,
                                         gz_headerp head));
/*
     inflateGetHeader() requests that gzip header information be stored in the
   provided gz_header structure.  inflateGetHeader() may be called after
   inflateInit2() or inflateReset(), and before the first call of inflate().
   As inflate() processes the gzip stream, head->done is zero until the header
   is completed, at which time head->done is set to one.  If a zlib stream is
   being decoded, then head->done is set to -1 to indicate that there will be
   no gzip header information forthcoming.  Note that Z_BLOCK or Z_TREES can be
   used to force inflate() to return immediately after header processing is
   complete and before any actual data is decompressed.

     The text, time, xflags, and os fields are filled in with the gzip header
   contents.  hcrc is set to true if there is a header CRC.  (The header CRC
   was valid if done is set to one.) If extra is not Z_NULL, then extra_max
   contains the maximum number of bytes to write to extra.  Once done is true,
   extra_len contains the actual extra field length, and extra contains the
   extra field, or that field truncated if extra_max is less than extra_len.
   If name is not Z_NULL, then up to name_max characters are written there,
   terminated with a zero unless the length is greater than name_max.  If
   comment is not Z_NULL, then up to comm_max characters are written there,
```

```
   terminated with a zero unless the length is greater than comm_max.  When any
   of extra, name, or comment are not Z_NULL and the respective field is not
   present in the header, then that field is set to Z_NULL to signal its
   absence.  This allows the use of deflateSetHeader() with the returned
   structure to duplicate the header.  However if those fields are set to
   allocated memory, then the application will need to save those pointers
   elsewhere so that they can be eventually freed.

     If inflateGetHeader is not used, then the header information is simply
   discarded.  The header is always checked for validity, including the header
   CRC if present.  inflateReset() will reset the process to discard the header
   information.  The application would need to call inflateGetHeader() again to
   retrieve the header from the next gzip stream.

     inflateGetHeader returns Z_OK if success, or Z_STREAM_ERROR if the source
   stream state was inconsistent.
*/

/*
ZEXTERN int ZEXPORT inflateBackInit OF((z_streamp strm, int windowBits,
                                        unsigned char FAR *window));

     Initialize the internal stream state for decompression using inflateBack()
   calls.  The fields zalloc, zfree and opaque in strm must be initialized
   before the call.  If zalloc and zfree are Z_NULL, then the default library-
   derived memory allocation routines are used.  windowBits is the base two
   logarithm of the window size, in the range 8..15.  window is a caller
   supplied buffer of that size.  Except for special applications where it is
   assured that deflate was used with small window sizes, windowBits must be 15
   and a 32K byte window must be supplied to be able to decompress general
   deflate streams.

     See inflateBack() for the usage of these routines.

     inflateBackInit will return Z_OK on success, Z_STREAM_ERROR if any of
   the parameters are invalid, Z_MEM_ERROR if the internal state could not be
   allocated, or Z_VERSION_ERROR if the version of the library does not match
   the version of the header file.
*/

                                z_const unsigned char FAR * FAR *));
typedef int (*out_func) OF((void FAR *, unsigned char FAR *, unsigned));

ZEXTERN int ZEXPORT inflateBack OF((z_streamp strm,
                                    in_func in, void FAR *in_desc,
                                    out_func out, void FAR *out_desc));
/*
     inflateBack() does a raw inflate with a single call using a call-back
   interface for input and output.  This is potentially more efficient than
   inflate() for file i/o applications, in that it avoids copying between the
   output and the sliding window by simply making the window itself the output
   buffer.  inflate() can be faster on modern CPUs when used with large
   buffers.  inflateBack() trusts the application to not change the output
   buffer passed by the output function, at least until inflateBack() returns.

     inflateBackInit() must be called first to allocate the internal state
   and to initialize the state with the user-provided window buffer.
   inflateBack() may then be used multiple times to inflate a complete, raw
   deflate stream with each call.  inflateBackEnd() is then called to free the
   allocated state.

     A raw deflate stream is one with no zlib or gzip header or trailer.
   This routine would normally be used in a utility that reads zip or gzip
   files and writes out uncompressed files.  The utility would decode the
   header and process the trailer on its own, hence this routine expects only
```

```
1051    the raw deflate stream to decompress.  This is different from the normal
1052    behavior of inflate(), which expects either a zlib or gzip header and
1053    trailer around the deflate stream.

1055      inflateBack() uses two subroutines supplied by the caller that are then
1056    called by inflateBack() for input and output.  inflateBack() calls those
1057    routines until it reads a complete deflate stream and writes out all of the
1058    uncompressed data, or until it encounters an error.  The function's
1059    parameters and return types are defined above in the in_func and out_func
1060    typedefs.  inflateBack() will call in(in_desc, &buf) which should return the
1061    number of bytes of provided input, and a pointer to that input in buf.  If
1062    there is no input available, in() must return zero--buf is ignored in that
1063    case--and inflateBack() will return a buffer error.  inflateBack() will call
1064    out(out_desc, buf, len) to write the uncompressed data buf[0..len-1].  out()
1065    should return zero on success, or non-zero on failure.  If out() returns
1066    non-zero, inflateBack() will return with an error.  Neither in() nor out()
1067    are permitted to change the contents of the window provided to
1068    inflateBackInit(), which is also the buffer that out() uses to write from.
1069    The length written by out() will be at most the window size.  Any non-zero
1070    amount of input may be provided by in().

1072      For convenience, inflateBack() can be provided input on the first call by
1073    setting strm->next_in and strm->avail_in.  If that input is exhausted, then
1074    in() will be called.  Therefore strm->next_in must be initialized before
1075    calling inflateBack().  If strm->next_in is Z_NULL, then in() will be called
1076    immediately for input.  If strm->next_in is not Z_NULL, then strm->avail_in
1077    must also be initialized, and then if strm->avail_in is not zero, input will
1078    initially be taken from strm->next_in[0 ..  strm->avail_in - 1].

1080      The in_desc and out_desc parameters of inflateBack() is passed as the
1081    first parameter of in() and out() respectively when they are called.  These
1082    descriptors can be optionally used to pass any information that the caller-
1083    supplied in() and out() functions need to do their job.

1085      On return, inflateBack() will set strm->next_in and strm->avail_in to
1086    pass back any unused input that was provided by the last in() call.  The
1087    return values of inflateBack() can be Z_STREAM_END on success, Z_BUF_ERROR
1088    if in() or out() returned an error, Z_DATA_ERROR if there was a format error
1089    in the deflate stream (in which case strm->msg is set to indicate the nature
1090    of the error), or Z_STREAM_ERROR if the stream was not properly initialized.
1091    In the case of Z_BUF_ERROR, an input or output error can be distinguished
1092    using strm->next_in which will be Z_NULL only if in() returned an error.  If
1093    strm->next_in is not Z_NULL, then the Z_BUF_ERROR was due to out() returning
1094    non-zero.  (in() will always be called before out(), so strm->next_in is
1095    assured to be defined if out() returns non-zero.) Note that inflateBack()
1096    cannot return Z_OK.

1215                         /* gzip file access functions */

1217 /*
1218      This library supports reading and writing files in gzip (.gz) format with
1219    an interface similar to that of stdio, using the functions that start with
1220    "gz".  The gzip format is different from the zlib format.  gzip is a gzip
1221    wrapper, documented in RFC 1952, wrapped around a deflate stream.
1222 */

1224 typedef struct gzFile_s *gzFile;    /* semi-opaque gzip file descriptor */

1226 /*
1227 ZEXTERN gzFile ZEXPORT gzopen OF((const char *path, const char *mode));

1229      Opens a gzip (.gz) file for reading or writing.  The mode parameter is as
1230    in fopen ("rb" or "wb") but can also include a compression level ("wb9") or
1231    a strategy: 'f' for filtered data as in "wb6f", 'h' for Huffman-only
1232    compression as in "wb1h", 'R' for run-length encoding as in "wb1R", or 'F'
1233    for fixed code compression as in "wb9F".  (See the description of
1234    deflateInit2 for more information about the strategy parameter.)  'T' will
1235    request transparent writing or appending with no compression and not using
1236    the gzip format.

1238      "a" can be used instead of "w" to request that the gzip stream that will
1239    be written be appended to the file.  "+" will result in an error, since
1240    reading and writing to the same gzip file is not supported.  The addition of
1241    "x" when writing will create the file exclusively, which fails if the file
1242    already exists.  On systems that support it, the addition of "e" when
1243    reading or writing will set the flag to close the file on an execve() call.

1245      These functions, as well as gzip, will read and decode a sequence of gzip
1246    streams in a file.  The append function of gzopen() can be used to create
1247    such a file.  (Also see gzflush() for another way to do this.)  When
1248    appending, gzopen does not test whether the file begins with a gzip stream,
```

```
1249    nor does it look for the end of the gzip streams to begin appending.  gzopen
1250    will simply append a gzip stream to the existing file.

1252      gzopen can be used to read a file which is not in gzip format; in this
1253    case gzread will directly read from the file without decompression.  When
1254    reading, this will be detected automatically by looking for the magic two-
1255    byte gzip header.

1257      gzopen returns NULL if the file could not be opened, if there was
1258    insufficient memory to allocate the gzFile state, or if an invalid mode was
1259    specified (an 'r', 'w', or 'a' was not provided, or '+' was provided).
1260    errno can be checked to determine if the reason gzopen failed was that the
1261    file could not be opened.
1262 */

1264 ZEXTERN gzFile ZEXPORT gzdopen OF((int fd, const char *mode));
1265 /*
1266      gzdopen associates a gzFile with the file descriptor fd.  File descriptors
1267    are obtained from calls like open, dup, creat, pipe or fileno (if the file
1268    has been previously opened with fopen).  The mode parameter is as in gzopen.

1270      The next call of gzclose on the returned gzFile will also close the file
1271    descriptor fd, just like fclose(fdopen(fd, mode)) closes the file descriptor
1272    fd.  If you want to keep fd open, use fd = dup(fd_keep); gz = gzdopen(fd,
1273    mode);.  The duplicated descriptor should be saved to avoid a leak, since
1274    gzdopen does not close fd if it fails.  If you are using fileno() to get the
1275    file descriptor from a FILE *, then you will have to use dup() to avoid
1276    double-close()ing the file descriptor.  Both gzclose() and fclose() will
1277    close the associated file descriptor, so they need to have different file
1278    descriptors.

1280      gzdopen returns NULL if there was insufficient memory to allocate the
1281    gzFile state, if an invalid mode was specified (an 'r', 'w', or 'a' was not
1282    provided, or '+' was provided), or if fd is -1.  The file descriptor is not
1283    used until the next gz* read, write, seek, or close operation, so gzdopen
1284    will not detect if fd is invalid (unless fd is -1).
1285 */

1287 ZEXTERN int ZEXPORT gzbuffer OF((gzFile file, unsigned size));
1288 /*
1289      Set the internal buffer size used by this library's functions.  The
1290    default buffer size is 8192 bytes.  This function must be called after
1291    gzopen() or gzdopen(), and before any other calls that read or write the
1292    file.  The buffer memory allocation is always deferred to the first read or
1293    write.  Two buffers are allocated, either both of the specified size when
1294    writing, or one of the specified size and the other twice that size when
1295    reading.  A larger buffer size of, for example, 64K or 128K bytes will
1296    noticeably increase the speed of decompression (reading).

1298      The new buffer size also affects the maximum length for gzprintf().

1300      gzbuffer() returns 0 on success, or -1 on failure, such as being called
1301    too late.

1307    of deflateInit2 for the meaning of these parameters.

1309      gzsetparams returns Z_OK if success, or Z_STREAM_ERROR if the file was not
1310    opened for writing.
1311 */

1313 ZEXTERN int ZEXPORT gzread OF((gzFile file, voidp buf, unsigned len));
1314 /*
```

```
1315      Reads the given number of uncompressed bytes from the compressed file.  If
1316    the input file is not in gzip format, gzread copies the given number of
1317    bytes into the buffer directly from the file.

1319      After reaching the end of a gzip stream in the input, gzread will continue
1320    to read, looking for another gzip stream.  Any number of gzip streams may be
1321    concatenated in the input file, and will all be decompressed by gzread().
1322    If something other than a gzip stream is encountered after a gzip stream,
1323    that remaining trailing garbage is ignored (and no error is returned).

1325      gzread can be used to read a gzip file that is being concurrently written.
1326    Upon reaching the end of the input, gzread will return with the available
1327    data.  If the error code returned by gzerror is Z_OK or Z_BUF_ERROR, then
1328    gzclearerr can be used to clear the end of file indicator in order to permit
1329    gzread to be tried again.  Z_OK indicates that a gzip stream was completed
1330    on the last gzread.  Z_BUF_ERROR indicates that the input file ended in the
1331    middle of a gzip stream.  Note that gzread does not return -1 in the event
1332    of an incomplete gzip stream.  This error is deferred until gzclose(), which
1333    will return Z_BUF_ERROR if the last gzread ended in the middle of a gzip
1334    stream.  Alternatively, gzerror can be used before gzclose to detect this
1335    case.

1337      gzread returns the number of uncompressed bytes actually read, less than
1338    len for end of file, or -1 for error.
1339 */

1341 ZEXTERN int ZEXPORT gzwrite OF((gzFile file,
1342                                 voidpc buf, unsigned len));
1343 /*
1344      Writes the given number of uncompressed bytes into the compressed file.
1345    gzwrite returns the number of uncompressed bytes written or 0 in case of
1346    error.
1347 */

1349 ZEXTERN int ZEXPORTVA gzprintf Z_ARG((gzFile file, const char *format, ...));
1350 /*
1351      Converts, formats, and writes the arguments to the compressed file under
1352    control of the format string, as in fprintf.  gzprintf returns the number of
1353    uncompressed bytes actually written, or 0 in case of error.  The number of
1354    uncompressed bytes written is limited to 8191, or one less than the buffer
1355    size given to gzbuffer().  The caller should assure that this limit is not
1356    exceeded.  If it is exceeded, then gzprintf() will return an error (0) with
1357    nothing written.  In this case, there may also be a buffer overflow with
1358    unpredictable consequences, which is possible only if zlib was compiled with
1359    the insecure functions sprintf() or vsprintf() because the secure snprintf()
1360    or vsnprintf() functions were not available.  This can be determined using
1361    zlibCompileFlags().
1362 */

1401 /*
1402      Push one character back onto the stream to be read as the first character
1403    on the next read.  At least one character of push-back is allowed.
1404    gzungetc() returns the character pushed, or -1 on failure.  gzungetc() will
1405    fail if c is -1, and may fail if a character has been pushed but not read
1406    yet.  If gzungetc is used immediately after gzopen or gzdopen, at least the
1407    output buffer size of pushed characters is allowed.  (See gzbuffer above.)
1408    The pushed character will be discarded if the stream is repositioned with
1409    gzseek() or gzrewind().
1410 */

1412 ZEXTERN int ZEXPORT gzflush OF((gzFile file, int flush));
1413 /*
1414      Flushes all pending output into the compressed file.  The parameter flush
1415    is as in the deflate() function.  The return value is the zlib error number
1416    (see function gzerror below).  gzflush is only permitted when writing.

1418      If the flush parameter is Z_FINISH, the remaining data is written and the
1419    gzip stream is completed in the output.  If gzwrite() is called again, a new
1420    gzip stream will be started in the output.  gzread() is able to read such
1421    concatented gzip streams.

1423      gzflush should be called only when strictly necessary because it will
1424    degrade compression if called too often.
1425 */

1427 /*
1428 ZEXTERN z_off_t ZEXPORT gzseek OF((gzFile file,
1429                                    z_off_t offset, int whence));

1431      Sets the starting position for the next gzread or gzwrite on the given
1432    compressed file.  The offset represents a number of bytes in the
1433    uncompressed data stream.  The whence parameter is defined as in lseek(2);
1434    the value SEEK_END is not supported.

1436      If the file is opened for reading, this function is emulated but can be
1437    extremely slow.  If the file is opened for writing, only forward seeks are
1438    supported; gzseek then compresses a sequence of zeroes up to the new
1439    starting position.

1441      gzseek returns the resulting offset location as measured in bytes from
1442    the beginning of the uncompressed stream, or -1 in case of error, in
1443    particular if the file is opened for writing and the new starting position
1444    would be before the current position.
1445 */
```

```
ZEXTERN int ZEXPORT    gzrewind OF((gzFile file));
/*
     Rewinds the given file. This function is supported only for reading.

     gzrewind(file) is equivalent to (int)gzseek(file, 0L, SEEK_SET)
*/

/*
ZEXTERN z_off_t ZEXPORT    gztell OF((gzFile file));

     Returns the starting position for the next gzread or gzwrite on the given
   compressed file.  This position represents a number of bytes in the
   uncompressed data stream, and is zero when starting, even if appending or
   reading a gzip stream from the middle of a file using gzdopen().

     gztell(file) is equivalent to gzseek(file, 0L, SEEK_CUR)
*/

/*
ZEXTERN z_off_t ZEXPORT gzoffset OF((gzFile file));

     Returns the current offset in the file being read or written.  This offset
   includes the count of bytes that precede the gzip stream, for example when
   appending or when using gzdopen() for reading.  When reading, the offset
   does not include as yet unused buffered input.  This information can be used
   for a progress indicator.  On error, gzoffset() returns -1.
*/

ZEXTERN int ZEXPORT gzeof OF((gzFile file));
/*
     Returns true (1) if the end-of-file indicator has been set while reading,
   false (0) otherwise.  Note that the end-of-file indicator is set only if the
   read tried to go past the end of the input, but came up short.  Therefore,
   just like feof(), gzeof() may return false even if there is no more data to
   read, in the event that the last read request was for the exact number of
   bytes remaining in the input file.  This will happen if the input file size
   is an exact multiple of the buffer size.

     If gzeof() returns true, then the read functions will return no more data,
   unless the end-of-file indicator is reset by gzclearerr() and the input file
   has grown since the previous end of file was detected.
*/

ZEXTERN int ZEXPORT gzdirect OF((gzFile file));
/*
     Returns true (1) if file is being copied directly while reading, or false
   (0) if file is a gzip stream being decompressed.

     If the input file is empty, gzdirect() will return true, since the input
   does not contain a gzip stream.

     If gzdirect() is used immediately after gzopen() or gzdopen() it will
   cause buffers to be allocated to allow reading the file to determine if it
   is a gzip file.  Therefore if gzbuffer() is used, it should be called before
   gzdirect().

     When writing, gzdirect() returns true (1) if transparent writing was
   requested ("wT" for the gzopen() mode), or false (0) otherwise.  (Note:
   gzdirect() is not needed when writing.  Transparent writing must be
   explicitly requested, so the application already knows the answer.  When
   linking statically, using gzdirect() will include all of the zlib code for
   gzip file reading and decompression, which may not be desired.)
*/

ZEXTERN int ZEXPORT    gzclose OF((gzFile file));
/*
```

```
     Flushes all pending output if necessary, closes the compressed file and
   deallocates the (de)compression state.  Note that once file is closed, you
   cannot call gzerror with file, since its structures have been deallocated.
   gzclose must not be called more than once on the same file, just as free
   must not be called more than once on the same allocation.

     gzclose will return Z_STREAM_ERROR if file is not valid, Z_ERRNO on a
   file operation error, Z_MEM_ERROR if out of memory, Z_BUF_ERROR if the
   last read ended in the middle of a gzip stream, or Z_OK on success.
*/

ZEXTERN int ZEXPORT gzclose_r OF((gzFile file));
ZEXTERN int ZEXPORT gzclose_w OF((gzFile file));
/*
     Same as gzclose(), but gzclose_r() is only for use when reading, and
   gzclose_w() is only for use when writing or appending.  The advantage to
   using these instead of gzclose() is that they avoid linking in zlib
   compression or decompression code that is not used when only reading or only
   writing respectively.  If gzclose() is used, then both compression and
   decompression code will be included the application when linking to a static
   zlib library.
*/

ZEXTERN const char * ZEXPORT gzerror OF((gzFile file, int *errnum));
/*
     Returns the error message for the last error which occurred on the given
   compressed file.  errnum is set to zlib error number.  If an error occurred
   in the file system and not in the compression library, errnum is set to
   Z_ERRNO and the application may consult errno to get the exact error code.

     The application must not modify the returned string.  Future calls to
   this function may invalidate the previously returned string.  If file is
   closed, then the string previously returned by gzerror will no longer be
   available.

     gzerror() should be used to distinguish errors from end-of-file for those
   functions above that do not distinguish those cases in their return values.
*/

ZEXTERN void ZEXPORT gzclearerr OF((gzFile file));
/*
     Clears the error and end-of-file flags for file.  This is analogous to the
   clearerr() function in stdio.  This is useful for continuing to read a gzip
   file that is being written concurrently.
*/

#endif /* !Z_SOLO */

                        /* checksum functions */

/*
     These functions are not related to compression but are exported
   anyway because they might be useful in applications using the compression
   library.
*/

ZEXTERN uLong ZEXPORT adler32 OF((uLong adler, const Bytef *buf, uInt len));
/*
     Update a running Adler-32 checksum with the bytes buf[0..len-1] and
   return the updated checksum.  If buf is Z_NULL, this function returns the
   required initial value for the checksum.

     An Adler-32 checksum is almost as reliable as a CRC32 but can be computed
   much faster.

   Usage example:
```

```
1580      uLong adler = adler32(0L, Z_NULL, 0);

1582      while (read_buffer(buffer, length) != EOF) {
1583        adler = adler32(adler, buffer, length);
1584      }
1585      if (adler != original_adler) error();
1586 */

1588 /*
1589 ZEXTERN uLong ZEXPORT adler32_combine OF((uLong adler1, uLong adler2,
1590                                           z_off_t len2));

1592      Combine two Adler-32 checksums into one.  For two sequences of bytes, seq1
1593    and seq2 with lengths len1 and len2, Adler-32 checksums were calculated for
1594    each, adler1 and adler2.  adler32_combine() returns the Adler-32 checksum of
1595    seq1 and seq2 concatenated, requiring only adler1, adler2, and len2.  Note
1596    that the z_off_t type (like off_t) is a signed integer.  If len2 is
1597    negative, the result has no meaning or utility.
1598 */

1600 ZEXTERN uLong ZEXPORT crc32   OF((uLong crc, const Bytef *buf, uInt len));
1601 /*
1602      Update a running CRC-32 with the bytes buf[0..len-1] and return the
1603    updated CRC-32.  If buf is Z_NULL, this function returns the required
1604    initial value for the crc.  Pre- and post-conditioning (one’s complement) is
1605    performed within this function so it shouldn’t be done by the application.

1607    Usage example:

1609      uLong crc = crc32(0L, Z_NULL, 0);

1611      while (read_buffer(buffer, length) != EOF) {
1612        crc = crc32(crc, buffer, length);
1613      }
1614      if (crc != original_crc) error();
1615 */

1617 /*
1618 ZEXTERN uLong ZEXPORT crc32_combine OF((uLong crc1, uLong crc2, z_off_t len2));

1620      Combine two CRC-32 check values into one.  For two sequences of bytes,
1621    seq1 and seq2 with lengths len1 and len2, CRC-32 check values were
1622    calculated for each, crc1 and crc2.  crc32_combine() returns the CRC-32
1623    check value of seq1 and seq2 concatenated, requiring only crc1, crc2, and
1624    len2.
1625 */

-.TH ZLIB 3 "28 Apr 2013"
+.TH LIBZ 3 "28 Apr 2013"
 .SH NAME
-zlib \- compression/decompression library
+libz \- compression/decompression library
 .SH SYNOPSIS
 [see
 .I zlib.h
 for full description]
 .SH DESCRIPTION
 The
-.I zlib
+.I libz (zlib)
 library is a general purpose data compression library.
 The code is thread safe, assuming that the standard library functions
 used are thread safe, such as memory allocation routines.
```

Patch origin: in-house
Patch status: Solaris-specific; not suitable for upstream

ZLIB renames *.o file into *.lo before it links them info shared
library. We need to do same to *.o.bc files so they are recognized by
Parfait during linking.

Downside of it is that Parfait will analyze also these separate object
files.

.TH LIBZ 3 "28 Apr 2013"
.SH NAME
libz \- compression/decompression library
.SH SYNOPSIS
[see
.I zlib.h
for full description]
.SH DESCRIPTION
The
.I libz (zlib)
library is a general purpose data compression library.
The code is thread safe, assuming that the standard library functions
used are thread safe, such as memory allocation routines.
It provides in-memory compression and decompression functions,
including integrity checks of the uncompressed data.
This version of the library supports only one compression method (deflation)
but other algorithms may be added later
with the same stream interface.
.LP
Compression can be done in a single step if the buffers are large enough
or can be done by repeated calls of the compression function.
In the latter case,
the application must provide more input and/or consume the output
(providing more output space) before each call.
.LP
The library also supports reading and writing files in
.IR gzip (1)
(.gz) format
with an interface similar to that of stdio.
.LP
The library does not install any signal handler.
The decoder checks the consistency of the compressed data,
so the library should never crash even in the case of corrupted input.
.LP
All functions of the compression library are documented in the file
.IR zlib.h .
The distribution source includes examples of use of the library
in the files
.I test/example.c
and
.IR test/minigzip.c,
as well as other examples in the
.IR examples/
directory.
.LP
Changes to this version are documented in the file
.I ChangeLog
that accompanies the source.
.LP
.I zlib
is available in Java using the java.util.zip package:
.IP
http://java.sun.com/developer/technicalArticles/Programming/compression/
.LP
A Perl interface to
.IR zlib ,
written by Paul Marquess (pmqs@cpan.org),
is available at CPAN (Comprehensive Perl Archive Network) sites,
including:
.IP
```

```
http://search.cpan.org/~pmqs/IO-Compress-Zlib/
.LP
A Python interface to
.IR zlib ,
written by A.M. Kuchling (amk@magnet.com),
is available in Python 1.5 and later versions:
.IP
http://docs.python.org/library/zlib.html
.LP
.I zlib
is built into
.IR tcl:
.IP
http://wiki.tcl.tk/4610
.LP
An experimental package to read and write files in .zip format,
written on top of
.I zlib
by Gilles Vollant (info@winimage.com),
is available at:
.IP
http://www.winimage.com/zLibDll/minizip.html
and also in the
.I contrib/minizip
directory of the main
.I zlib
source distribution.
.SH "SEE ALSO"
The
.I zlib
web site can be found at:
.IP
http://zlib.net/
.LP
The data format used by the zlib library is described by RFC
(Request for Comments) 1950 to 1952 in the files:
.IP
http://tools.ietf.org/html/rfc1950 (for the zlib header and trailer format)
.br
http://tools.ietf.org/html/rfc1951 (for the deflate compressed data format)
.br
http://tools.ietf.org/html/rfc1952 (for the gzip header and trailer format)
.LP
Mark Nelson wrote an article about
.I zlib
for the Jan. 1997 issue of  Dr. Dobb's Journal;
a copy of the article is available at:
.IP
http://marknelson.us/1997/01/01/zlib-engine/
.SH "REPORTING PROBLEMS"
Before reporting a problem,
please check the
.I zlib
web site to verify that you have the latest version of
.IR zlib ;
otherwise,
obtain the latest version and see if the problem still exists.
Please read the
.I zlib
FAQ at:
.IP
http://zlib.net/zlib_faq.html
.LP
before asking for help.
Send questions and/or comments to zlib@gzip.org,
or (for the Windows DLL version) to Gilles Vollant (info@winimage.com).
```

```
.SH AUTHORS
Version 1.2.8
Copyright (C) 1995-2013 Jean-loup Gailly (jloup@gzip.org)
and Mark Adler (madler@alumni.caltech.edu).
.LP
This software is provided "as-is,"
without any express or implied warranty.
In no event will the authors be held liable for any damages
arising from the use of this software.
See the distribution directory with respect to requirements
governing redistribution.
The deflate format used by
.I zlib
was defined by Phil Katz.
The deflate and
.I zlib
specifications were written by L. Peter Deutsch.
Thanks to all the people who reported problems and suggested various
improvements in
.IR zlib ;
who are too numerous to cite here.
