  24 # Audit Event Database
  25 #
  26 # File Format:
  27 #
  28 # event number:event name:event description:event classes (comma separated)
  29 #
  30 # Used to map audit events to audit classes for preselection and post-selection.
  31 # Used by TCB programs that write audit records to preselect audit events
  32 #     based on event to class mappings.
  33 #
  34 # NOTE: several events are obsolete but must continue to be defined here for
  35 # compatibility reasons. Obsolete events are defined in the "no" (invalid)
  36 # class to indicate they will not be generated.  Other events in the "no"
  37 # class which are not obsolete (but are in this class for other reasons),
  38 # are individually noted with a comment for explanation.
  39 #
  40 # System Adminstrators: Do NOT modify or add events with an event number less
  41 #   than 32768. These are reserved by the system.
  42 #
  43 #     0         Reserved as an invalid event number.
  44 #     1 - 2047  Reserved for the Solaris Kernel events.
  45 #  2048 - 32767 Reserved for the Solaris TCB programs.
  46 # 32768 - 65535 Available for third party TCB applications.
  47 #
  48 #
  49 # Allocation of reserved kernel events:
  50 # (NOTE: the kernel event table, and possibly MAX_KEVENTS, must be updated
  51 # in audit_kevents.h when changes are made to kernel events.)
  52 #           1 -   511   allocated for Solaris
  53 #         512 -  2047   (reserved but not allocated)
  54 #
  55 # Allocation of user level audit events:
  56 #        2048 -  5999   (reserved but not allocated)
  57 #        6000 -  9999   allocated for Solaris
  58 #       10000 - 32767   (reserved but not allocated)
```

```

<specification>

<!-- comments are displayed to stderr if debug is on -->
<debug set="off"/>

    <!-- The order of events is arbitrary EXCEPT generic events must
         precede their instances -->
       <!-- The order of entries within an event determine the order
            data is defined in the external API -->
            <!-- The order of internal / external is arbitrary -->

<!--
        tags:
                        The following top level tags are defined:
                        <event> <token> <msg_list> <debug>

        event           defines an audit record
                        - id is the record id from audit_uevents.h
                        - reorder="yes" or "no".  (default is "no").
                          if "yes" then the order of the tokens to be
                          output does not match the order of the data
                          input.  (see order attribute of <entry>)
                        - header defines the header file to contain the external
                          definitions for this event type.  The header file
                          name is adt_event_N.h, where N is the value supplied
                          header="0" is for "stable" events, > 0 for new ones.
                          with this attribute. (header="1").
                        - idNo is the number associated with the external
                          name of this event. (For AUE_login, ADT_login is
                          the external name and idNo is the value for
                          ADT_login.)
                        - omit is by default 'no' (i.e., don't omit) and can be
                          'always' or 'JNI'.  In the latter case, C interface
                          code is generated but neither Java nor JNI code is.
                        - included text is just a comment
                        Within an event block, the following tags are defined:
                        <entry>, <debug>, <altname>, <title>, <program>, <see>

        altname         defines the internal name of an audit record; if
                        omitted, the internal name is the same as the
                        external name.

        title,          these tags are used by auditrecord(1M) build to create
        program,        audit_record_attr database from adt events.
        see             Following example demonstrates their semantics:

                        auditrecord -p passwd
                        passwd          <-   <title>
                          program     various              See passwd(1)
                                        ^-   <program>          ^-   <see>
                          event ID    6163                 AUE_passwd
                          class       lo                   (0x00001000)
                              header
                              subject
                              [text]                       username...
                                                                ^-   <comment>
                              return

                        If the length of string in any of the given
                        elements is longer than defined, the string is
                        silently truncated to the defined length in the
                        auditrecord(1M) runtime:

                               element <= max (non-truncated) string length
                               title   <= 46
                               program <= 20
                               see     <= 39
                               comment <= unlimited
                               token   <= 28

        entry           defines the correspondence between the data
                        supplied by the caller and the token to be
                        output.
                        - id is the data name that shows up in the structures
                          of adt_event.h  If it is a comma separated list,
                          it is the list of names of data to be associated
                          with one output token.  (See <external>, below)
                        Within an entry block, the following tags are defined:
                        <internal>, <external>, <debug>, <comment>

        internal        defines the token to be generated.
                        - token is a name that must also be defined with
                          a <token> tag elsewhere in this file.  (order is
                          not important).
                        - order="some number" determines the order of the
                          tokens to be output, starting with 1.  The subject
                          token is normally order="1".  The use is to insure
                          that the order of fields listed in adt_event.h does
                          not change when we arbitrarily change the order of
                          tokens.  If the <event reorder="yes"> is not set,
                          order is ignored.
                        - format is a printf-like string that will be used
                          in to format the data supplied by the user.

        external        defines the data to be supplied for creating the
                        token defined via <internal>
                        - opt is one of four values:  "required", "optional",
                          "obsolete", or "none".  The first two values
```

```
                          indicate that this token's data must or may
                          be supplied by the user; the third value is
                          equivalent to "optional" but shows in the
                          comment that this field is no longer used;
                          the forth value indicates that this token
                          does not require any user-supplied data.  If
                          data is required, then a token is always
                          output, while optional data is output only
                          if data is supplied.
                        - type describes the C data type to be associated
                          with the <entry id="dataName">.  The following
                          data types are representative:

                                au_asid_t (uint32_t)
                                char
                                char * (blank is optional)
                                char ** (blank is optional)
                                fd_t (int, a file descriptor)
                                uint_t, int, int32_t, uid_t, gid_t
                                uid_t *, gid_t *
                                long, ulong_t
                                m_label_t *
                                pid_t
                                priv_set_t *
                                uint16_t, unit32_t, uint64_t
                                uint32_t *, uint32_t[], uint64_t *
                                msg  (not a C type, see below)

                        Below is what Tony said.  Above seems to be
                        what is implemented
                                char
                                char * (blank is optional)
                                char ** (blank is optional)
                                int, uid_t, gid_t
                                int *, uid_t *, gid_t *
                                msg  (not a C type, see below)
                                time_t
                                uint, uint *

                          The msg type refers to an enumerated type
                          that must be defined via a <msg> description
                          else where in this file. The syntax is
                          special.  Example: <external opt="optional"
                          type="msg login_text"/> "login_text" is the
                          id of a <msg_list> descriptor given
                          elsewhere in this file.

                        If the <entry> id is a list, the type must also
                        be a comma-separated list, where the types are
                        in the same order as the id's.
                        If the type is an array, its length must be given
                        explicitly.

        comment         Used by auditrecord(1M) build to generate
                        audit_record_attr. Comment is explanation note
                        printed with token type. Colon (':') may not be
                        used in a comment. See example above for other
                        tags related to auditrecord(1M).

        token           Define allowed token names.
                        - id is the name of token; this name is used
                        as an <internal> id.
                        - a token id name may not end in digits.
                        - usage is an optional value.  At present, only
                          "TSOL" is defined; it means that this data is
                          to be used only in Trusted Solaris implementations.
```

```
                        See also example above for "token" tag relation to
                        the auditrecord(1M) output.

        msg_list        Define a set of text strings.
                        - id is the name to be used for this group of text
                          strings in adt_event.h
                        - header is as defined for <event>
                        - start is a number where produced enum type begins;
                          ensure msg lists do not overlap
                        Within a msg_list block, <msg> and <debug> are defined.
                        The order of <msg> tags in a msg_list is reflected
                        directly in adt_event.h. Also add ADT_LIST_<<id>> to
                        enum adt_msg_list in adt_xlate.h.

        msg             Define one string.
                        - id is the name to be used in the enum describing
                          this set of strings.  Convention:  use upper case.
                        The content (text between <msg> and </msg>) is the
                        actual string.  Extra white space, including line
                        feeds, is ignored.  If empty, no output token
                        is generated unless the <external> opt attribute is
                        set to "required", in which case a blank text token
                        is generated.
                        Within a msg block, <debug> is defined, but has not been
                        tested and may have no effect.

        debug           This turns on/off debug messages during the processing
                        of the xml data.  It affects the block within which it
                        is defined.
                        - set may have one of two values:  "on" or "off".  If
                          set is omitted, the debug state for the current block
                          is toggled.
                        The use of the <debug> tag does not affect the output
                        of data to the various files created, but does generate
                        potentially large amounts of output to stderr.

     This is still in use by SMC.  See AUE_generic_login.  When
     either SMC is fixed to stop using this, or SMC goes away.
     REMOVE this stuff and the corresponding AUE_generic_login
     message field.

     Message list for the various authentication events, such
     as AUE_login and AUE_admin_authenticate.  Add new entries
     at the end.  The order of msg_list entries and the order
     of msg entries both affect the names in adt.h and the value
     of the associated enumerated types.

     Each of these messages except NO_MSG is also in the failure_attribute
     list; the difference is that the messages below use a text token
     in the audit record, while the failure_attribute messages are
     associated with the return value of the return token.

     This list is deprecated; please don't use text tokens for error
     messages.

987 # NOTE: libc.so.1 must be linked with the minimal crti.o and crtn.o
988 # modules whose source is provided in the $(SRC)/lib/common directory.
989 # This must be done because otherwise the Sun C compiler would insert
990 # its own versions of these modules and those versions contain code
991 # to call out to C++ initialization functions.  Such C++ initialization
992 # functions can call back into libc before thread initialization is
993 # complete and this leads to segmentation violations and other problems.
994 # Since libc contains no C++ code, linking with the minimal crti.o and
995 # crtn.o modules is safe and avoids the problems described above.

1030 # NOTE: libc.so.1 must be linked with the minimal crti.o and crtn.o
1031 # modules whose source is provided in the $(SRC)/lib/common directory.
1032 # This must be done because otherwise the Sun C compiler would insert
1033 # its own versions of these modules and those versions contain code
1034 # to call out to C++ initialization functions.  Such C++ initialization
1035 # functions can call back into libc before thread initialization is
1036 # complete and this leads to segmentation violations and other problems.
1037 # Since libc contains no C++ code, linking with the minimal crti.o and
1038 # crtn.o modules is safe and avoids the problems described above.

1067 # NOTE: libc.so.1 must be linked with the minimal crti.o and crtn.o
1068 # modules whose source is provided in the $(SRC)/lib/common directory.
1069 # This must be done because otherwise the Sun C compiler would insert
1070 # its own versions of these modules and those versions contain code
1071 # to call out to C++ initialization functions.  Such C++ initialization
1072 # functions can call back into libc before thread initialization is
1073 # complete and this leads to segmentation violations and other problems.
1074 # Since libc contains no C++ code, linking with the minimal crti.o and
1075 # crtn.o modules is safe and avoids the problems described above.

 113 /*
 114  * Long reasons must all parse/read correctly in the following contexts:
 115  *
 116  * "A service instance transitioned state: %s."
 117  * "A service failed: %s."
 118  * "Reason: %s."
 119  * "The service transitioned state (%s) and ..."
 120  *
 121  * With the exception of restart_str_none they must also fit the following
 122  * moulds:
 123  *
 124  * "An instance transitioned because %s, and ..."
```

```
 * "An instance transitioned to <new-state> because %s, and ..."
 *
 * Note that whoever is rendering the long message must provide the
 * terminal punctuation - don't include it here.  Similarly, do not
 * provide an initial capital letter in reason-long.
 *
 * The long reason strings are Volatile - within the grammatical constraints
 * above we may improve them as need be.  The intention is that a consumer
 * may blindly render the string along the lines of the above examples,
 * but has no other guarantees as to the exact wording.  Long reasons
 * are localized.
 *
 * We define revisions of the set of short reason strings in use.  Within
 * a given revision, all short reasons are Committed.  Consumers must check
 * the revision in use before relying on the semantics of the short reason
 * codes - if the version exceeds that which they are familiar with they should
 * fail gracefully.  Having checked for version compatability, a consumer
 * is assured that
 *
 *      "short_reason_A iff semantic_A", provided:
 *
 *              . the restarter uses this short reason code at all,
 *              . the short reason is not "none" (which a restarter could
 *                specifiy for any transition semantics)
 *
 * To split/refine such a Committed semantic_A into further cases,
 * we are required to bump the revision number.  This should be an
 * infrequent occurence.  If you bump the revision number you may
 * need to make corresponding changes in any source that calls
 * restarter_str_version (e.g., FMA event generation).
 *
 * To add additional reasons to the set you must also bump the version
 * number.

/*
 * There are 3 parts to librestart.
 *      1) The event protocol from the master restarter to its delegates.
 *      2) A functional interface for updating the repository.
 *      3) Convenience functions for common restarter tasks.
 *
 * Event protocol
 *      We need a reliable event protocol, as there's no way to define
 *      restarter events as idempotent.
 *
 *      Currently using sysevent channels as the reliable event implementation.
 *      This could change if the implementation proves unsuitable, but
 *      the API defined here should abstract anything but a change in
 *      the fundamental event model.
 *
 *      We offer functions to tease apart the event rather than generic
 *      nvpair interfaces. This is because each event type has a well-
```

/*
 * Internal interfaces for snapshot creation:
 *      _scf_snapshot_take_new(), _scf_snapshot_take_new_named(), and
 *      _scf_snapshot_take_attach() create a set of snaplevels
 *      containing frozen versions of both the instance's property groups and
 *      its parent service's property groups. _scf_snapshot_take_new() and
 *      _scf_snapshot_take_new_named() create a new snapshot to which the
 *      new snaplevels are attached, while _scf_snapshot_take_attach()
 *      attaches the new snaplevels to a pre-existing snapshot.
 *
 *      _scf_snapshot_take_new_named() records the passed in names into the
 *      snaplevel instead of the instance and service name.  This creates
 *      an inconsistency, which should be resolved by using
 *      _scf_snapshot_attach() to attach the new snaplevels to a snapshot
 *      underneath the appropriate instance.  The first snapshot can
 *      then be deleted.
 *
 *      _scf_snapshot_attach(snap1, snap2) points snap2 at the snaplevels
 *      pointed to by snap1.  After a call to either
 *      _scf_snapshot_take_attach(snap1, snap2) or
 *      _scf_snapshot_attach(inst, snap), scf_snapshot_update() will be
 *      required for any open references to snap or snap2 to see the new
 *      snaplevels.
 *
 *      _scf_snapshot_delete() deletes the snapshot object.  While
 *      snaplevels, being only loosely connected to snapshots, stay
 *      around until they are no longer referenced, any references *through
 *      this snapshot object* will be invalidated.
 *
 * _scf_snapshot_take_new() can fail with at least _HANDLE_MISMATCH,
 * _CONNECTION_BROKEN, _INVALID_ARGUMENT, _NO_RESOURCES, _PERMISSION_DENIED,
 * _NOT_SET, _EXISTS.
 *
 * _scf_snapshot_take_new_named() can fail with at least _HANDLE_MISMATCH,
 * _CONNECTION_BROKEN, _INVALID_ARGUMENT, _NO_RESOURCES, _PERMISSION_DENIED,
 * _NOT_SET, _EXISTS.
 *

/*
 * Walks all the instances matching a given fmri list.  Each fmri in the array
 * can be one of the following:
 *
 *      - Full instance name
 *      - Full service name
 *      - Full property group or property name
 *      - Partial service or instance name
 *      - A globbed pattern
 *
 * The matching rules for partial fmris are a slightly more complex.  We allow
 * for any substring anchored at the end of the instance or service name,
 * provided it begins with a complete element in the fmri.  For example, given
 * the fmri "svc:/system/filesystem/local:default", any of the following would
 * be acceptable matches: 'default', 'local', 'local:default',
 * 'filesystem/local'.  The following would not be acceptable:
 * 'system/filesystem', 'filesystem/loc', 'system/local'.  Possible flag values:
 *
 *      SCF_WALK_MULTIPLE       Allow individual arguments to correspond to
 *                              multiple instances.
 *
```

```
 *      SCF_WALK_LEGACY         Walk legacy services (indicated by a non-NULL
 *                              propery group).
 *
 *      SCF_WALK_SERVICE        If the user specifies a service, pass the
 *                              service to the callback without iterating over
 *                              its instances.
 *
 *      SCF_WALK_PROPERTY       Allow FMRIs which match property groups or
 *                              individual properties.  Incompatible with
 *                              SCF_WALK_LEGACY.
 *
 *      SCF_WALK_NOINSTANCE     Walk only services.  Must be used in
 *                              conjunction with SCF_WALK_SERVICE.
 *
 *      SCF_WALK_EXPLICIT       Walk only services if the match is exact
 *                              else return instances. Must be used in
 *                              conjunction with SCF_WALK_SERVICE.
 *
 *      SCF_WALK_UNIPARTIAL     Can be combined with SCF_WALK_MULTIPLE
 *                              so that an error is returned if a partial
 *                              fmri matches multiple instances, unless
 *                              a wildcard match is also used.
 *
 * If no arguments are given, then all instances in the service graph are
 * walked.
 *
 * The second to last parameter is set to UU_EXIT_FATAL if one of the arguments
 * is an invalid FMRI or matches multiple FMRIs when SCF_WALK_MULTIPLE is not
 * set.
 *
 * The last parameter is a user-supplied error function that is called when
 * reporting invalid arguments.

 * Interfaces for bulk access to SMF-stored configuration.
 *
 * Each scf_propvec_t represents a single property to be read (with
 * scf_read_propvec) or written (with scf_write_propvec).
 *
 * The fields of a scf_propvec_t have the following meanings:
 *
 *   pv_prop - the name of the property
```

```
 *   pv_desc - a description string (optional; to be consumed by the caller)
 *   pv_type - the type of the property
 *   pv_ptr  - where to store the data read, or a pointer to the data to
 *             be written
 *   pv_aux  - additional data influencing the interpretation of pv_ptr
 *
 * The meaning of pv_ptr and pv_aux depends on the type of property.  For:
 *
 *   boolean - if pv_aux is 0, pv_ptr is a pointer to a boolean_t
 *             if pv_aux is non-0, pv_ptr is a pointer to a uint64_t,
 *             where pv_aux indicates the bit holding the truth value.
 *   count   - pv_ptr is a pointer to a uint64_t; pv_aux is unused
 *   integer - pv_ptr is a pointer to an int64_t; pv_aux is unused
 *   time    - pv_ptr is a pointer to an scf_time_t; pv_aux is unused
 *   opaque  - pv_ptr is a pointer to an scf_opaque_t; pv_aux is unused
 *   strings - (scf_read_propvec) pv_ptr is a pointer to a char *
 *             (scf_write_propvec) pv_ptr is a pointer to an array of char
 *             (both) pv_aux is unused

1169  * The goal of this routine is to cause the index file update and the
1170  * document save to happen as an atomic operation.  We do the document
1171  * first, saving a backup copy using a hard link; if that succeeds, we go
1172  * on to the index.  If that fails, we roll the document back into place.
1173  *
1174  * Strategy:
1175  *
1176  * New zone 'foo' configuration:
1177  *      Create tmpfile (zonecfg.xxxxxx)
1178  *      Write XML to tmpfile
1179  *      Rename tmpfile to xmlfile (zonecfg.xxxxxx -> foo.xml)
1180  *      Add entry to index file
```

```
 *      If it fails, delete foo.xml, leaving nothing behind.
 *
 * Save existing zone 'foo':
 *      Make backup of foo.xml -> .backup
 *      Create tmpfile (zonecfg.xxxxxx)
 *      Write XML to tmpfile
 *      Rename tmpfile to xmlfile (zonecfg.xxxxxx -> foo.xml)
 *      Modify index file as needed
 *      If it fails, recover from .backup -> foo.xml
 *
 * Rename 'foo' to 'bar':
 *      Create tmpfile (zonecfg.xxxxxx)
 *      Write XML to tmpfile
 *      Rename tmpfile to xmlfile (zonecfg.xxxxxx -> bar.xml)

7351 /*
7352  * The following three routines implement a simple locking mechanism to
7353  * ensure that only one instance of zoneadm at a time is able to manipulate
7354  * a given zone.  The lock is built on top of an fcntl(2) lock of
7355  * [<altroot>]/var/run/zones/<zonename>.zoneadm.lock.  If a zoneadm instance
7356  * can grab that lock, it is allowed to manipulate the zone.
7357  *
7358  * Since zoneadm may call external applications which in turn invoke
7359  * zoneadm again, we introduce the notion of "lock inheritance".  Any
7360  * instance of zoneadm that has another instance in its ancestry is assumed
7361  * to be acting on behalf of the original zoneadm, and is thus allowed to
7362  * manipulate its zone.
7363  *
7364  * This inheritance is implemented via the _ZONEADM_LOCK_HELD environment
7365  * variable.  When zoneadm is granted a lock on its zone, this environment
7366  * variable is set to 1.  When it releases the lock, the variable is set to
7367  * 0.  Since a child process inherits its parent’s environment, checking
```

  61         Historically, the deleted-device element denoted a used-to-be
  62         device element.  This was used to keep track of device elements
  63         deleted or modified by the user, and to cleanse /dev of such
  64         entries at next zone boot.

  66         With the ability to now configure devices dynamically, this
  67         requirement no longer exists, but this element MUST remain in
  68         perpetuity, since it is possible that an upgraded zone could
  69         carry a deleted-device element, and would therefore fail XML
  70         validation if removed

  41 .SH DESCRIPTION
  42 .sp
  42 .LP
  43 The link-editor, \fBld\fR, combines relocatable object files by resolving
  44 symbol references to symbol definitions, together with performing relocations.
  45 \fBld\fR operates in two modes, static or dynamic, as governed by the \fB-d\fR
  46 option. In all cases, the output of \fBld\fR is left in the file \fBa.out\fR by
  47 default. See NOTES.
  48 .sp
  49 .LP
  50 In dynamic mode, \fB-dy\fR, the default, relocatable object files that are
  51 provided as arguments are combined to produce an executable object file. This
  52 file is linked at execution with any shared object files that are provided as
  53 arguments. If the \fB-G\fR option is specified, relocatable object files are
  54 combined to produce a shared object. Without the \fB-G\fR option, a dynamic
```

```
  55 executable is created.
  56 .sp
  57 .LP
  58 In static mode, \fB-dn\fR, relocatable object files that are provided as
  59 arguments are combined to produce a static executable file. If the \fB-r\fR
  60 option is specified, relocatable object files are combined to produce one
  61 relocatable object file. See \fBStatic Executables\fR.
  62 .sp
  63 .LP
  64 Dynamic linking is the most common model for combining relocatable objects, and
  65 the eventual creation of processes within Solaris. This environment tightly
  66 couples the work of the link-editor and the runtime linker, \fBld.so.1\fR(1).
  67 Both of these utilities, together with their related technologies and
  68 utilities, are extensively documented in the \fILinker and Libraries Guide\fR.
  69 .sp
  70 .LP
  71 If any argument is a library, \fBld\fR by default searches the library exactly
  72 once at the point the library is encountered on the argument list. The library
  73 can be either a shared object or relocatable archive. See \fBar.h\fR(3HEAD)).
  74 .sp
  75 .LP
  76 A shared object consists of an indivisible, whole unit that has been generated
  77 by a previous link-edit of one or more input files. When the link-editor
  78 processes a shared object, the entire contents of the shared object become a
  79 logical part of the resulting output file image. The shared object is not
  80 physically copied during the link-edit as its actual inclusion is deferred
  81 until process execution. This logical inclusion means that all symbol entries
  82 defined in the shared object are made available to the link-editing process.
  83 See Chapter 4, \fIShared Objects,\fR in \fILinker and Libraries Guide\fR
  84 .sp
  85 .LP
  86 For an archive library, \fBld\fR loads only those routines that define an
  87 unresolved external reference. \fBld\fR searches the symbol table of the
  88 archive library sequentially to resolve external references that can be
  89 satisfied by library members. This search is repeated until no external
  90 references can be resolved by the archive. Thus, the order of members in the
  91 library is functionally unimportant, unless multiple library members exist that
  92 define the same external symbol. Archive libraries that have interdependencies
  93 can require multiple command line definitions, or the use of one of the
  94 \fB-z\fR \fBrescan\fR options. See \fIArchive Processing\fR in \fILinker and
  95 Libraries Guide\fR.
  96 .sp
  97 .LP
  98 \fBld\fR is a cross link-editor, able to link 32-bit objects or 64-bit objects,
  99 for Sparc or x86 targets. \fBld\fR uses the \fBELF\fR class and machine type of
 100 the first relocatable object on the command line to govern the mode in which to
 101 operate. The mixing of 32-bit objects and 64-bit objects is not permitted.
 102 Similarly, only objects of a single machine type are allowed. See the
 103 \fB-32\fR, \fB-64\fR and \fB-z target\fR options, and the \fBLD_NOEXEC_64\fR
 104 environment variable.
 105 .SS "Static Executables"
 107 .sp
 106 .LP
 107 The creation of static executables has been discouraged for many releases. In
 108 fact, 64-bit system archive libraries have never been provided. Because a
 109 static executable is built against system archive libraries, the executable
 110 contains system implementation details. This self-containment has a number of
 111 drawbacks.
 112 .RS +4
 113 .TP
 114 .ie t \(bu
 115 .el o
 116 The executable is immune to the benefits of system patches delivered as shared
 117 objects. The executable therefore, must be rebuilt to take advantage of many
 118 system improvements.
 119 .RE
```

```
.RS +4
.TP
.ie t \(bu
.el o
The ability of the executable to run on future releases can be compromised.
.RE
.RS +4
.TP
.ie t \(bu
.el o
The duplication of system implementation details negatively affects system
performance.
.RE
.sp
.LP
With Solaris 10, 32-bit system archive libraries are no longer provided.
Without these libraries, specifically \fBlibc.a\fR, the creation of static
executables is no longer achievable without specialized system knowledge.
However, the capability of \fBld\fR to process static linking options, and the
processing of archive libraries, remains unchanged.
.SH OPTIONS
.sp
.LP
The following options are supported.
.sp
.ne 2
.na
\fB\fB-32\fR | \fB-64\fR\fR
.ad
.sp .6
.RS 4n
Creates a 32-bit, or 64-bit object.
.sp
By default, the class of the object being generated is determined from the
first \fBELF\fR object processed from the command line. If no objects are
specified, the class is determined by the first object encountered within the
first archive processed from the command line. If there are no objects or
archives, the link-editor creates a 32-bit object.
.sp
The \fB-64\fR option is required to create a 64-bit object solely from a
mapfile.
.sp
This \fB-32\fR or \fB-64\fR options can also be used in the rare case of
linking entirely from an archive that contains a mixture of 32 and 64-bit
objects. If the first object in the archive is not the class of the object that
is required to be created, then the \fB-32\fR or \fB-64\fR option can be used
to direct the link-editor. See \fIThe 32-bit link-editor and 64-bit
link-editor\fR in \fILinker and Libraries Guide\fR.
.RE

.sp
.ne 2
.na
\fB\fB-a\fR\fR
.ad
.sp .6
.RS 4n
In static mode only, produces an executable object file. Undefined references
are not permitted. This option is the default behavior for static mode. The
\fB-a\fR option can not be used with the \fB-r\fR option. See \fBStatic
Executables\fR under DESCRIPTION.
.RE

.sp
.ne 2
.na
```

```
\fB\fB-b\fR\fR
.ad
.sp .6
.RS 4n
In dynamic mode only, provides no special processing for dynamic executable
relocations that reference symbols in shared objects. Without the \fB-b\fR
option, the link-editor applies techniques within a dynamic executable so that
the text segment can remain read-only. One technique is the creation of special
position-independent relocations for references to functions that are defined
in shared objects. Another technique arranges for data objects that are defined
in shared objects to be copied into the memory image of an executable at
runtime.
.sp
The \fB-b\fR option is intended for specialized dynamic objects and is not
recommended for general use. Its use suppresses all specialized processing
required to ensure an object's shareability, and can even prevent the
relocation of 64-bit executables.
.RE

.sp
.ne 2
.na
\fB\fB-B\fR \fBdirect\fR | \fBnodirect\fR\fR
.ad
.sp .6
.RS 4n
These options govern direct binding. \fB-B\fR \fBdirect\fR establishes direct
binding information by recording the relationship between each symbol reference
together with the dependency that provides the definition. In addition, direct
binding information is established between each symbol reference and an
associated definition within the object being created. The runtime linker uses
this information to search directly for a symbol in the associated object
rather than to carry out a default symbol search.
.sp
Direct binding information can only be established to dependencies specified
with the link-edit. Thus, you should use the \fB-z\fR \fBdefs\fR option.
Objects that wish to interpose on symbols in a direct binding environment
should identify themselves as interposers with the \fB-z\fR \fBinterpose\fR
option. The use of \fB-B\fR \fBdirect\fR enables \fB-z\fR \fBlazyload\fR for
all dependencies.
.sp
The \fB-B\fR \fBnodirect\fR option prevents any direct binding to the
interfaces offered by the object being created. The object being created can
continue to directly bind to external interfaces by specifying the \fB-z\fR
\fBdirect\fR option. See Appendix D, \fIDirect Bindings,\fR in \fILinker and
Libraries Guide\fR.
.RE

.sp
.ne 2
.na
\fB\fB-B\fR \fBdynamic\fR | \fBstatic\fR\fR
.ad
.sp .6
.RS 4n
Options governing library inclusion. \fB-B\fR \fBdynamic\fR is valid in dynamic
mode only. These options can be specified any number of times on the command
line as toggles: if the \fB-B\fR \fBstatic\fR option is given, no shared
objects are accepted until \fB-B\fR \fBdynamic\fR is seen. See the \fB-l\fR
option.
.RE

.sp
.ne 2
.na
\fB\fB-B\fR \fBeliminate\fR\fR
```

```
.ad
.sp .6
.RS 4n
Causes any global symbols, not assigned to a version definition, to be
eliminated from the symbol table. Version definitions can be supplied by means
of a \fBmapfile\fR to indicate the global symbols that should remain visible in
the generated object. This option achieves the same symbol elimination as the
\fIauto-elimination\fR directive that is available as part of a \fBmapfile\fR
version definition. This option can be useful when combining versioned and
non-versioned relocatable objects. See also the \fB-B\fR \fBlocal\fR option and
the \fB-B\fR \fBreduce\fR option. See \fIDefining Additional Symbols with a
mapfile\fR in \fILinker and Libraries Guide\fR.
.RE

.sp
.ne 2
.na
\fB\fB-B\fR \fBgroup\fR\fR
.ad
.sp .6
.RS 4n
Establishes a shared object and its dependencies as a group. Objects within the
group are bound to other members of the group at runtime. This mode is similar
to adding the object to the process by using \fBdlopen\fR(3C) with the
\fBRTLD_GROUP\fR mode. An object that has an explicit dependency on a object
identified as a group, becomes a member of the group.
.sp
As the group must be self contained, use of the \fB-B\fR \fBgroup\fR option
also asserts the \fB-z\fR \fBdefs\fR option.
.RE

.sp
.ne 2
.na
\fB\fB-B\fR \fBlocal\fR\fR
.ad
.sp .6
.RS 4n
Causes any global symbols, not assigned to a version definition, to be reduced
to local. Version definitions can be supplied by means of a \fBmapfile\fR to
indicate the global symbols that should remain visible in the generated object.
This option achieves the same symbol reduction as the \fIauto-reduction\fR
directive that is available as part of a \fBmapfile\fR version definition. This
option can be useful when combining versioned and non-versioned relocatable
objects. See also the \fB-B\fR \fBeliminate\fR option and the \fB-B\fR
\fBreduce\fR option. See \fIDefining Additional Symbols with a mapfile\fR in
\fILinker and Libraries Guide\fR.
.RE

.sp
.ne 2
.na
\fB\fB-B\fR \fBreduce\fR\fR
.ad
.sp .6
.RS 4n
When generating a relocatable object, causes the reduction of symbolic
information defined by any version definitions. Version definitions can be
supplied by means of a \fBmapfile\fR to indicate the global symbols that should
remain visible in the generated object. By default, when a relocatable object
is generated, version definitions are only recorded in the output image. The
actual reduction of symbolic information is carried out when the object is used
in the construction of a dynamic executable or shared object. The \fB-B\fR
\fBreduce\fR option is applied automatically when a dynamic executable or
shared object is created.
.RE
```

```
.sp
.ne 2
.na
\fB\fB-B\fR \fBsymbolic\fR\fR
.ad
.sp .6
.RS 4n
In dynamic mode only. When building a shared object, binds references to global
symbols to their definitions, if available, within the object. Normally,
references to global symbols within shared objects are not bound until runtime,
even if definitions are available. This model allows definitions of the same
symbol in an executable or other shared object to override the object's own
definition. \fBld\fR issues warnings for undefined symbols unless \fB-z\fR
\fBdefs\fR overrides.
.sp
The \fB-B\fR \fBsymbolic\fR option is intended for specialized dynamic objects
and is not recommended for general use. To reduce the runtime relocation
processing that is required an object, the creation of a version definition is
recommended.

507 .na
508 \fB\fB--library\fR \fIx\fR\fR
509 .ad
510 .sp .6
511 .RS 4n
512 Searches a library \fBlib\fR\fIx\fR\fB\&.so\fR or \fBlib\fR\fIx\fR\fB\&.a\fR,
513 the conventional names for shared object and archive libraries, respectively.
514 In dynamic mode, unless the \fB-B\fR \fBstatic\fR option is in effect, \fBld\fR
```

```
515 searches each directory specified in the library search path for a
516 \fBlib\fR\fIx\fR\fB\&.so\fR or \fBlib\fR\fIx\fR\fB\&.a\fR file. The directory
517 search stops at the first directory containing either. \fBld\fR chooses the
518 file ending in \fB\&.so\fR if \fB-l\fR\fIx\fR expands to two files with names
519 of the form \fBlib\fR\fIx\fR\fB\&.so\fR and \fBlib\fR\fIx\fR\fB\&.a\fR. If no
520 \fBlib\fR\fIx\fR\fB\&.so\fR is found, then \fBld\fR accepts
521 \fBlib\fR\fIx\fR\fB\&.a\fR. In static mode, or when the \fB-B\fR \fBstatic\fR
522 option is in effect, \fBld\fR selects only the file ending in \fB\&.a\fR.
523 \fBld\fR searches a library when the library is encountered, so the placement
524 of \fB-l\fR is significant. See \fILinking With Additional Libraries\fR in
525 \fILinker and Libraries Guide\fR.

Specify whether the executable’s address space should be randomized on
execution.  If \fIstate\fR is "enabled" randomization will always occur when
this executable is run (regardless of inherited settings).  If \fIstate\fR is
"disabled" randomization will never occur when this executable is run.  If
\fIstate\fR is omitted, ASLR is enabled.

An executable that should simply use the settings inherited from its
environment should not use this flag at all.
.RE

.sp
.ne 2
.na
#endif /* ! codereview */
\fB\fB-z\fR \fBcombreloc\fR | \fBnocombreloc\fR\fR
.ad
.sp .6
.RS 4n
By default, \fBld\fR combines multiple relocation sections when building
executables or shared objects. This section combination differs from
relocatable objects, in which relocation sections are maintained in a
one-to-one relationship with the sections to which the relocations must be
applied. The \fB-z\fR \fBnocombreloc\fR option disables this merging of
relocation sections, and preserves the one-to-one relationship found in the
original relocatable objects.
.sp
\fBld\fR sorts the entries of data relocation sections by their symbol
reference. This sorting reduces runtime symbol lookup. When multiple relocation
sections are combined, this sorting produces the least possible relocation
overhead when objects are loaded into memory, and speeds the runtime loading of
dynamic objects.
.sp
Historically, the individual relocation sections were carried over to any
executable or shared object, and the \fB-z\fR \fBcombreloc\fR option was
required to enable the relocation section merging previously described.
Relocation section merging is now the default. The \fB-z\fR \fBcombreloc\fR
option is still accepted for the benefit of old build environments, but the
option is unnecessary, and has no effect.

\fB\fB-z\fR \fBinitfirst\fR\fR
```

```
.ad
.sp .6
.RS 4n
Marks the object so that its runtime initialization occurs before the runtime
initialization of any other objects brought into the process at the same time.
In addition, the object runtime finalization occurs after the runtime
finalization of any other objects removed from the process at the same time.
This option is only meaningful when building a shared object.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBinterpose\fR\fR
.ad
.sp .6
.RS 4n
Marks the object as an interposer. At runtime, an object is identified as an
explicit interposer if the object has been tagged using the \fB-z interpose\fR
option. An explicit interposer is also established when an object is loaded
using the \fBLD_PRELOAD\fR environment variable. Implicit interposition can
occur because of the load order of objects, however, this implicit
interposition is unknown to the runtime linker. Explicit interposition can
ensure that interposition takes place regardless of the order in which objects
are loaded. Explicit interposition also ensures that the runtime linker
searches for symbols in any explicit interposers when direct bindings are in
effect.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBlazyload\fR | \fBnolazyload\fR\fR
.ad
.sp .6
.RS 4n
Enables or disables the marking of dynamic dependencies to be lazily loaded.
Dynamic dependencies which are marked \fBlazyload\fR are not loaded at initial
process start-up. These dependencies are delayed until the first binding to the
object is made. \fBNote:\fR Lazy loading requires the correct declaration of
dependencies, together with associated runpaths for each dynamic object used
within a process. See \fILazy Loading of Dynamic Dependencies\fR in \fILinker
and Libraries Guide\fR.
.RE

\fB\fB-z\fR \fBld32\fR=\fIarg1\fR,\fIarg2\fR,...\fR
.ad
.br
.na
\fB\fB-z\fR \fBld64\fR=\fIarg1\fR,\fIarg2\fR,...\fR
.ad
.sp .6
.RS 4n
The class of the link-editor is affected by the class of the output file being
created and by the capabilities of the underlying operating system. The
\fB-z\fR \fBld\fR[\fB32\fR|\fB64\fR] options provide a means of defining any
link-editor argument. The defined argument is only interpreted, respectively,
by the 32-bit class or 64-bit class of the link-editor.
.sp
For example, support libraries are class specific, so the correct class of
support library can be ensured using:
.sp
.in +2
```

```
.nf
\fBld ... -z ld32=-Saudit32.so.1 -z ld64=-Saudit64.so.1 ...\fR
.fi
.in -2
.sp

The class of link-editor that is invoked is determined from the \fBELF\fR class
of the first relocatable file that is seen on the command line. This
determination is carried out \fBprior\fR to any \fB-z\fR
\fBld\fR[\fB32\fR|\fB64\fR] processing.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBloadfltr\fR\fR
.ad
.sp .6
.RS 4n
Marks a filter to indicate that filtees must be processed immediately at
runtime. Normally, filter processing is delayed until a symbol reference is
bound to the filter. The runtime processing of an object that contains this
flag mimics that which occurs if the \fBLD_LOADFLTR\fR environment variable is
in effect. See the \fBld.so.1\fR(1).

.ad
.sp .6
.RS 4n
Marks the object as not available to \fBdlopen\fR(3C), either as the object
specified by the \fBdlopen()\fR, or as any form of dependency required by the
object specified by the \fBdlopen()\fR. This option is only meaningful when
building a shared object.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBnodump\fR\fR
.ad
.sp .6
.RS 4n
Marks the object as not available to \fBdldump\fR(3C).
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBnoldynsym\fR\fR
.ad
.sp .6
.RS 4n
Prevents the inclusion of a \fB\&.SUNW_ldynsym\fR section in dynamic
executables or sharable libraries. The \fB\&.SUNW_ldynsym\fR section augments
the \fB\&.dynsym\fR section by providing symbols for local functions. Local
function symbols allow debuggers to display local function names in stack
traces from stripped programs. Similarly, \fBdladdr\fR(3C) is able to supply
more accurate results.
.sp
The \fB-z\fR \fBnoldynsym\fR option also prevents the inclusion of the two
symbol sort sections that are related to the \fB\&.SUNW_ldynsym\fR section. The
\fB\&.SUNW_dynsymsort\fR section provides sorted access to regular function and
variable symbols. The \fB\&.SUNW_dyntlssort\fR section provides sorted access
to thread local storage (\fBTLS\fR) variable symbols.
.sp
The \fB\&.SUNW_ldynsym\fR, \fB\&.SUNW_dynsymsort\fR, and
\fB\&.SUNW_dyntlssort\fR sections, which becomes part of the allocable text
segment of the resulting file, cannot be removed by \fBstrip\fR(1). Therefore,
the \fB-z\fR \fBnoldynsym\fR option is the only way to prevent their inclusion.
See the \fB-s\fR and \fB-z\fR \fBredlocsym\fR options.
.RE

.sp
.ne 2
```

```
.na
\fB\fB-z\fR \fBnopartial\fR\fR
.ad

.sp
.ne 2
.na
\fB\fB-z\fR \fBredlocsym\fR\fR
.ad
.sp .6
.RS 4n
Eliminates all local symbols except for the \fISECT\fR symbols from the symbol
```

```
table \fBSHT_SYMTAB\fR. All relocations that refer to local symbols are updated
to refer to the corresponding \fISECT\fR symbol. This option allows specialized
objects to greatly reduce their symbol table sizes. Eliminated local symbols
can reduce the \fB\&.stab*\fR debugging information that is generated using the
compiler drivers \fB-g\fR option. See the \fB-s\fR and \fB-z\fR \fBnoldynsym\fR
options.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBrelaxreloc\fR\fR
.ad
.sp .6
.RS 4n
\fBld\fR normally issues a fatal error upon encountering a relocation using a
symbol that references an eliminated COMDAT section. If \fB-z\fR
\fBrelaxreloc\fR is enabled, \fBld\fR instead redirects such relocations to the
equivalent symbol in the COMDAT section that was kept. \fB-z\fR
\fBrelaxreloc\fR is a specialized option, mainly of interest to compiler
authors, and is not intended for general use.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBrescan-now\fR\fR
.ad
.br
.na
\fB\fB-z\fR \fBrescan\fR\fR
.ad
.sp .6
.RS 4n
These options rescan the archive files that are provided to the link-edit. By
default, archives are processed once as the archives appear on the command
line. Archives are traditionally specified at the end of the command line so
that their symbol definitions resolve any preceding references. However,
specifying archives multiple times to satisfy their own interdependencies can
be necessary.
.sp
\fB-z\fR \fBrescan-now\fR is a positional option, and is processed by the
link-editor immediately when encountered on the command line. All archives seen
on the command line up to that point are immediately reprocessed in an attempt
to locate additional archive members that resolve symbol references. This
archive rescanning is repeated until a pass over the archives occurs in which
no new members are extracted.
.sp
\fB-z\fR \fBrescan\fR is a position independent option. The link-editor defers
the rescan operation until after it has processed the entire command line, and
then initiates a final rescan operation over all archives seen on the command
line. The \fB-z\fR \fBrescan\fR operation can interact          incorrectly
with objects that contain initialization (.init) or finalization (.fini)
sections, preventing the code in those sections from running. For this reason,
\fB-z\fR \fBrescan\fR is deprecated, and use of \fB-z\fR \fBrescan-now\fR is
advised.
.RE

.ad
.sp .6
.RS 4n
Defines an archive rescan group. This is a positional construct, and is
processed by the link-editor immediately upon encountering the closing
delimiter option.  Archives found within the group delimiter options are
reprocessed as a group in an attempt to locate  additional archive members that
resolve symbol references. This archive rescanning  is repeated  until a  pass
over the archives On the occurs in  which no  new  members are extracted.
Archive rescan groups cannot be nested.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBtarget=sparc|x86\fR \fI\fR\fR
.ad
.sp .6
.RS 4n
Specifies the machine type for the output object. Supported targets are Sparc
and x86. The 32-bit machine type for the specified target is used unless the
\fB-64\fR option is also present, in which case the corresponding 64-bit
machine type is used. By default, the machine type of the object being
generated is determined from the first \fBELF\fR object processed from the
command line. If no objects are specified, the machine type is determined by
the first object encountered within the first archive processed from the
command line. If there are no objects or archives, the link-editor assumes the
native machine. This option is useful when creating an object directly with
\fBld\fR whose input is solely from a \fBmapfile\fR. See the \fB-M\fR option.
It can also be useful in the rare case of linking entirely from an archive that
contains objects of different machine types for which the first object is not
of the desired machine type. See \fIThe 32-bit link-editor and 64-bit
link-editor\fR in \fILinker and Libraries Guide\fR.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBtext\fR\fR
.ad
.sp .6
.RS 4n
In dynamic mode only, forces a fatal error if any relocations against
non-writable, allocatable sections remain. For historic reasons, this mode is
not the default when building an executable or shared object. However, its use
is recommended to ensure that the text segment of the dynamic object being
built is shareable between multiple running processes. A shared text segment
incurs the least relocation overhead when loaded into memory. See
\fIPosition-Independent Code\fR in \fILinker and Libraries Guide\fR.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBtextoff\fR\fR
.ad
.sp .6
.RS 4n
In dynamic mode only, allows relocations against all allocatable sections,
including non-writable ones. This mode is the default when building a shared
object.
.RE
```

```
.sp
.ne 2
.na
\fB\fB-z\fR \fBtextwarn\fR\fR
.ad
.sp .6
.RS 4n
In dynamic mode only, lists a warning if any relocations against non-writable,
allocatable sections remain. This mode is the default when building an
executable.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR \fBverbose\fR\fR
.ad
.sp .6
.RS 4n
This option provides additional warning diagnostics during a link-edit.
Presently, this option conveys suspicious use of displacement relocations. This
option also conveys the restricted use of static \fBTLS\fR relocations when
building shared objects. In future, this option might be enhanced to provide
additional diagnostics that are deemed too noisy to be generated by default.
.RE

.sp
.ne 2
.na
\fB\fB-z\fR\fBwrap=\fR\fIsymbol\fR\fR
.ad
.br
.na
\fB\fB-wrap=\fR \fIsymbol\fR\fR
.ad
.br
.na
\fB\fB--wrap=\fR \fIsymbol\fR\fR
.ad
.sp .6
.RS 4n
Rename undefined references to \fIsymbol\fR in order to allow wrapper code to
be linked into the output object without having to modify source code. When
\fB-z wrap\fR is specified, all undefined references to \fIsymbol\fR are
modified to reference \fB__wrap_\fR\fIsymbol\fR, and all references to
\fB__real_\fR\fIsymbol\fR are modified to reference \fIsymbol\fR. The user is
expected to provide an object containing the \fB__wrap_\fR\fIsymbol\fR
function. This wrapper function can call \fB__real_\fR\fIsymbol\fR in order to
reference the actual function being wrapped.
.sp
The following is an example of a wrapper for the \fBmalloc\fR(3C) function:
.sp
.in +2
.nf
void *
__wrap_malloc(size_t c)
{
        (void) printf("malloc called with %zu\en", c);
        return (__real_malloc(c));
}
.fi
.in -2

If you link other code with this file using \fB-z\fR \fBwrap=malloc\fR to
compile all the objects, then all calls to \fBmalloc\fR will call the function
```

```
\fB__wrap_malloc\fR instead. The call to \fB__real_malloc\fR will call the real
\fBmalloc\fR function.
.sp
The real and wrapped functions should be maintained in separate source files.
Otherwise, the compiler or assembler may resolve the call instead of leaving
that operation for the link-editor to carry out, and prevent the wrap from
occurring.
.RE

.SH ENVIRONMENT VARIABLES
 848 .sp
.ne 2
.na
\fB\fBLD_ALTEXEC\fR\fR
.ad
.sp .6
.RS 4n
An alternative link-editor path name. \fBld\fR executes, and passes control to
this alternative link-editor. This environment variable provides a generic
means of overriding the default link-editor that is called from the various
compiler drivers. See the \fB-z altexec64\fR option.
.RE

.sp
.ne 2
.na
\fB\fBLD_LIBRARY_PATH\fR\fR
.ad
.sp .6
.RS 4n
A list of directories in which to search for the libraries specified using the
\fB-l\fR option. Multiple directories are separated by a colon. In the most
general case, this environment variable contains two directory lists separated
by a semicolon:
.sp
.in +2
.nf
\fIdirlist1\fR\fB;\fR\fIdirlist2\fR
.fi
.in -2
.sp

If \fBld\fR is called with any number of occurrences of \fB-L\fR, as in:
.sp
.in +2
.nf
\fBld ... -L\fIpath1\fR ... -L\fIpathn\fR ...\fR
.fi
.in -2
.sp

then the search path ordering is:
.sp
.in +2
.nf
\fB\fIdirlist1 path1\fR ... \fIpathn dirlist2\fR LIBPATH\fR
.fi
.in -2
.sp

When the list of directories does not contain a semicolon, the list is
interpreted as \fIdirlist2\fR.
.sp
The \fBLD_LIBRARY_PATH\fR environment variable also affects the runtime linkers
search for dynamic dependencies.
.sp
```

This environment variable can be specified with a _32 or _64 suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes and overrides any non-suffixed version of the environment variable that is in effect.
.RE

.sp
.ne 2
.na
\fB\fBLD_NOEXEC_64\fR\fR
.ad
.sp .6
.RS 4n
Suppresses the automatic execution of the 64-bit link-editor. By default, the link-editor executes the 64-bit version when the \fBELF\fR class of the first relocatable file identifies a 64-bit object. The 64-bit image that a 32-bit link-editor can create, has some limitations. However, some link-edits might find the use of the 32-bit link-editor faster.

1847 .SH NOTES
1053 .sp
1848 .LP
1849 Default options applied by \fBld\fR are maintained for historic reasons. In
1850 today's programming environment, where dynamic objects dominate, alternative
1851 defaults would often make more sense. However, historic defaults must be
1852 maintained to ensure compatibility with existing program development
1853 environments. Historic defaults are called out wherever possible in this
1854 manual. For a description of the current recommended options, see Appendix A,
1855 \fILink-Editor Quick Reference,\fR in \fILinker and Libraries Guide\fR.
1856 .sp
1857 .LP
1858 If the file being created by \fBld\fR already exists, the file is unlinked
1859 after all input files have been processed. A new file with the specified name
1860 is then created. This allows \fBld\fR to create a new version of the file,
1861 while simultaneously allowing existing processes that are accessing the old
1862 file contents to continue running. If the old file has no other links, the disk
1863 space of the removed file is freed when the last process referencing the file
1864 terminates.
1865 .sp
1866 .LP
1867 The behavior of \fBld\fR when the file being created already exists was changed
1868 with \fBSXCE\fR build \fB43\fR. In older versions, the existing file was
1869 rewritten in place, an approach with the potential to corrupt any running
1870 processes that is using the file. This change has an implication for output
1871 files that have multiple hard links in the file system. Previously, all links
1872 would remain intact, with all links accessing the new file contents. The new
1873 \fBld\fR behavior \fBbreaks\fR such links, with the result that only the
1874 specified output file name references the new file. All the other links
1875 continue to reference the old file. To ensure consistent behavior, applications
1876 that rely on multiple hard links to linker output files should explicitly
1877 remove and relink the other file names.
```

\fIid\fR ...
.fi
.LP
.nf
\fB/usr/bin/psecflags\fR [\fI-F\fR] { \fIpid\fR | \fIcore\fR }
.fi
.LP
.nf
\fB/usr/bin/psecflags\fR \fI-l\fR
.fi

.SH "DESCRIPTION"
The first invocation of the \fBpsecflags\fR command runs the specified
\fIcommand\fR with the security-flags modified as described by the \fI-s\fR
argument.
.P
The second invocation modifies the security-flags of the processes described
by \fIidtype\fR and \fIid\fR according as described by the \fI-s\fR argument.
.P
The third invocation describes the security-flags of the specified processes
or core files.  The effective set is signified by '\fBE\fR', the inheritable
set by '\fBI\fR', the lower set by '\fBL\fR', and the upper set by '\fBU\fR'.
.P
The fourth invocation lists the supported process security-flags, documented
in \fBsecurity-flags\fR(5).

.SH "OPTIONS"
The following options are supported:
.sp
.ne 2
.na
\fB-e\fR
.ad
```

```
.RS 11n
Interpret the remaining arguments as a command line and run the command with
the security-flags specified with the \fI-s\fR flag.
.RE

.sp
.ne 2
.na
\fB-F\fR
.ad
.RS 11n
Force. Grab the target process even if another process has control.
.RE

.sp
.ne 2
.na
\fB-i\fR \fIidtype\fR
.ad
.RS 11n
This option, together with the \fIid\fR arguments specify one or more
processes whose security-flags will be modified. The interpretation of the
\fIid\fR arguments is based on \fIidtype\fR. If \fIidtype\fR is omitted the
default is \fBpid\fR.

Valid \fIidtype\fR options are:
.sp
.ne 2
.na
\fBall\fR
.ad
.RS 11n
The \fBpsecflags\fR command applies to all processes
.RE

.sp
.ne 2
.na
\fBcontract\fR, \fBctid\fR
.ad
.RS 11n
The security-flags of any process with a contract ID matching the \fIid\fR
arguments are modified.
.RE

.sp
.ne 2
.na
\fBgroup\fR, \fBgid\fR
.ad
.RS 11n
The security-flags of any process with a group ID matching the \fIid\fR
arguments are modified.
.RE

.sp
.ne 2
.na
\fBpid\fR
.ad
.RS 11n
The security-flags of any process with a process ID matching the \fIid\fR
arguments are modified. This is the default.
.RE

.sp
```

```
.ne 2
.na
\fBppid\fR
.ad
.RS 11n
The security-flags of any processes whose parent process ID matches the
\fIid\fR arguments are modified.
.RE

.sp
.ne 2
.na
\fBproject\fR, \fBprojid\fR
.ad
.RS 11n
The security-flags of any process whose project ID matches the \fIid\fR
arguments are modified.
.RE

.sp
.ne 2
.na
\fBsession\fR, \fBsid\fR
.ad
.RS 11n
The security-flags of any process whose session ID matches the \fIid\fR
arguments are modified.
.RE

.sp
.ne 2
.na
\fBtaskid\fR
.ad
.RS 11n
The security-flags of any process whose task ID matches the \fIid\fR arguments
are modified.
.RE

.sp
.ne 2
.na
\fBuser\fR, \fBuid\fR
.ad
.RS 11n
The security-flags of any process belonging to the users matching the \fIid\fR
arguments are modified.
.RE

.sp
.ne 2
.na
\fBzone\fR, \fBzoneid\fR
.ad
.RS 11n
The security-flags of any process running in the zones matching the given
\fIid\fR arguments are modified.
.RE
.RE

.sp
.ne 2
.na
\fB-l\fR
.ad
.RS 11n
```

```
List all supported process security-flags, described in
\fBsecurity-flags\fR(5).
.RE

.sp
.ne 2
.na
\fB-s\fR \fIspecification\fR
.ad
.RS 11n
Modify the process security-flags according to
\fIspecification\fR. Specifications take the form of a comma-separated list of
flags, optionally preceded by a '-' or '!'. Where '-' and '!' indicate that the
given flag should be removed from the specification.  The pseudo-flags "all",
"none" and "current" are supported, to indicate that all flags, no flags, or
the current set of flags (respectively) are to be included.
.P
By default, the inheritable flags are changed.  You may optionally specify the
set to change using their single-letter identifiers and an equals sign.
.P
For a list of valid security-flags, see \fBpsecflags -l\fR.
.RE

.SH "EXAMPLES"
.LP
\fBExample 1\fR Display the security-flags of the current shell.
.sp
.in +2
.nf
example$ \fBpsecflags $$\fR
100718: -sh
        E:      aslr
        I:      aslr
        L:      none
        U:      aslr,forbidnullmap,noexecstack
.fi
.in -2
.sp

.LP
\fBExample 2\fR Run a user command with ASLR enabled in addition to any
inherited security flags.
.sp
.in +2
.nf
example$ \fBpsecflags -s current,aslr -e /bin/sh\fR
$ psecflags $$
100724: -sh
        E:      none
        I:      aslr
        L:      none
        U:      aslr,forbidnullmap,noexecstack
.fi
.in -2
.sp

.LP
\fBExample 3\fR Remove aslr from the inheritable flags of all Bob's processes.
.sp
.in +2
.nf
example# \fBpsecflags -s current,-aslr -i uid bob\fR
.fi
.in -2

.LP
```

```
\fBExample 4\fR Add the aslr flag to the lower set, so that all future
child processes must have this flag set.
.sp
.in +2
.nf
example# \fBpsecflags -s L=current,aslr $$\fR
.fi
.in -2

.SH "EXIT STATUS"
The following exit values are returned:

.TP
\fB0\fR
.IP
Success.

.TP
\fBnon-zero\fR
.IP
An error has occured.

.SH "ATTRIBUTES"
.LP
See \fBattributes\fR(5) for descriptions of the following attributes:

  28 \fBzonecfg\fR help
  29 .fi

  31 .SH DESCRIPTION
  32 .sp
  32 .LP
  33 The \fBzonecfg\fR utility creates and modifies the configuration of a zone.
  34 Zone configuration consists of a number of resources and properties.
  35 .sp
  36 .LP
  37 To simplify the user interface, \fBzonecfg\fR uses the concept of a scope. The
  38 default scope is global.
  39 .sp
  40 .LP
  41 The following synopsis of the \fBzonecfg\fR command is for interactive usage:
  42 .sp
  43 .in +2
  44 .nf
  45 zonecfg \fB-z\fR \fIzonename subcommand\fR
  46 .fi
  47 .in -2
  48 .sp

  50 .sp
  51 .LP
  52 Parameters changed through \fBzonecfg\fR do not affect a running zone. The zone
  53 must be rebooted for the changes to take effect.
  54 .sp
  55 .LP
```

```
  56 In addition to creating and modifying a zone, the \fBzonecfg\fR utility can
  57 also be used to persistently specify the resource management settings for the
  58 global zone.
  59 .sp
  60 .LP
  61 In the following text, "rctl" is used as an abbreviation for "resource
  62 control". See \fBresource_controls\fR(5).
  63 .sp
  64 .LP
  65 Every zone is configured with an associated brand. The brand determines the
  66 user-level environment used within the zone, as well as various behaviors for
  67 the zone when it is installed, boots, or is shutdown. Once a zone has been
  68 installed the brand cannot be changed. The default brand is determined by the
  69 installed distribution in the global zone. Some brands do not support all of
  70 the \fBzonecfg\fR properties and resources. See the brand-specific man page for
  71 more details on each brand. For an overview of brands, see the \fBbrands\fR(5)
  72 man page.
  73 .SS "Resources"
  75 .sp
  74 .LP
  75 The following resource types are supported:
  76 .sp

.LP
As for the property values which are paired with these names, they are either
simple, complex, or lists. The type allowed is property-specific. Simple values
```

```
are strings, optionally enclosed within quotation marks. Complex values have
the syntax:
.sp
.in +2
.nf
(<\fIname\fR>=<\fIvalue\fR>,<\fIname\fR>=<\fIvalue\fR>,...)
.fi
.in -2
.sp

.sp
.LP
where each <\fIvalue\fR> is simple, and the <\fIname\fR> strings are unique
within a given property. Lists have the syntax:
.sp
.in +2
.nf
[<\fIvalue\fR>,...]
.fi
.in -2
.sp

.sp
.LP
where each <\fIvalue\fR> is either simple or complex. A list of a single value
(either simple or complex) is equivalent to specifying that value without the
list syntax. That is, "foo" is equivalent to "[foo]". A list can be empty
(denoted by "[]").
.sp
.LP
In interpreting property values, \fBzonecfg\fR accepts regular expressions as
specified in \fBfnmatch\fR(5). See \fBEXAMPLES\fR.
.sp
.LP
The property types are described as follows:
.sp
.ne 2
.na
\fBglobal: \fBzonename\fR\fR
.ad
.sp .6
.RS 4n
The name of the zone.
.RE

.sp
.ne 2
.na
\fBglobal: \fBzonepath\fR\fR
.ad
.sp .6
.RS 4n
Path to zone’s file system.
.RE

.sp
.ne 2
.na
\fBglobal: \fBautoboot\fR\fR
.ad
.sp .6
.RS 4n
Boolean indicating that a zone should be booted automatically at system boot.
Note that if the zones service is disabled, the zone will not autoboot,
regardless of the setting of this property. You enable the zones service with a
\fBsvcadm\fR command, such as:
```

```
.sp
.in +2
.nf
# \fBsvcadm enable svc:/system/zones:default\fR
.fi
.in -2
.sp

Replace \fBenable\fR with \fBdisable\fR to disable the zones service. See
\fBsvcadm\fR(1M).
.RE

.sp
.ne 2
.na
\fBglobal: \fBbootargs\fR\fR
.ad
.sp .6
.RS 4n
Arguments (options) to be passed to the zone bootup, unless options are
supplied to the "\fBzoneadm boot\fR" command, in which case those take
precedence. The valid arguments are described in \fBzoneadm\fR(1M).
.RE

.sp
.ne 2
.na
\fBglobal: \fBpool\fR\fR
.ad
.sp .6
.RS 4n
Name of the resource pool that this zone must be bound to when booted. This
property is incompatible with the \fBdedicated-cpu\fR resource.
.RE

.sp
.ne 2
.na
\fBglobal: \fBlimitpriv\fR\fR
.ad
.sp .6
.RS 4n
The maximum set of privileges any process in this zone can obtain. The property
should consist of a comma-separated privilege set specification as described in
\fBpriv_str_to_set\fR(3C). Privileges can be excluded from the resulting set by
preceding their names with a dash (-) or an exclamation point (!). The special
privilege string "zone" is not supported in this context. If the special string
"default" occurs as the first token in the property, it expands into a safe set
of privileges that preserve the resource and security isolation described in
\fBzones\fR(5). A missing or empty property is equivalent to this same set of
safe privileges.
.sp
The system administrator must take extreme care when configuring privileges for
a zone. Some privileges cannot be excluded through this mechanism as they are
required in order to boot a zone. In addition, there are certain privileges
which cannot be given to a zone as doing so would allow processes inside a zone
to unduly affect processes in other zones. \fBzoneadm\fR(1M) indicates when an
invalid privilege has been added or removed from a zone's privilege set when an
attempt is made to either "boot" or "ready" the zone.
.sp
See \fBprivileges\fR(5) for a description of privileges. The command "\fBppriv
-l\fR" (see \fBppriv\fR(1)) produces a list of all Solaris privileges. You can
specify privileges as they are displayed by \fBppriv\fR. In
\fBprivileges\fR(5), privileges are listed in the form
PRIV_\fIprivilege_name\fR. For example, the privilege \fIsys_time\fR, as you
would specify it in this property, is listed in \fBprivileges\fR(5) as
```

```
\fBPRIV_SYS_TIME\fR.
.RE

.sp
.ne 2
.na
\fBglobal: \fBbrand\fR\fR
.ad
.sp .6
.RS 4n
The zone's brand type.
.RE

.sp
.ne 2
.na
\fBglobal: \fBip-type\fR\fR
.ad
.sp .6
.RS 4n
A zone can either share the IP instance with the global zone, which is the
default, or have its own exclusive instance of IP.
.sp
This property takes the values \fBshared\fR and \fBexclusive\fR.
.RE

.sp
.ne 2
.na
\fBglobal: \fBhostid\fR\fR
.ad
.sp .6
.RS 4n
A zone can emulate a 32-bit host identifier to ease system consolidation. A
zone's \fBhostid\fR property is empty by default, meaning that the zone does
not emulate a host identifier. Zone host identifiers must be hexadecimal values
between 0 and FFFFFFFE. A \fB0x\fR or \fB0X\fR prefix is optional. Both
uppercase and lowercase hexadecimal digits are acceptable.
.RE

.sp
.ne 2
.na
\fB\fBfs\fR: dir, special, raw, type, options\fR
.ad
.sp .6
.RS 4n
Values needed to determine how, where, and so forth to mount file systems. See
\fBmount\fR(1M), \fBmount\fR(2), \fBfsck\fR(1M), and \fBvfstab\fR(4).
.RE

.sp
.ne 2
.na
\fB\fBnet\fR: address, physical, defrouter\fR
.ad
.sp .6
.RS 4n
The network address and physical interface name of the network interface. The
network address is one of:
.RS +4
.TP
.ie t \(bu
.el o
a valid IPv4 address, optionally followed by "\fB/\fR" and a prefix length;
.RE
```

```
.RS +4
.TP
.ie t \(bu
.el o
a valid IPv6 address, which must be followed by "\fB/\fR" and a prefix length;
.RE
.RS +4
.TP
.ie t \(bu
.el o
a host name which resolves to an IPv4 address.
.RE
Note that host names that resolve to IPv6 addresses are not supported.
.sp
The physical interface name is the network interface name.
.sp
The default router is specified similarly to the network address except that it
must not be followed by a \fB/\fR (slash) and a network prefix length.
.sp
A zone can be configured to be either exclusive-IP or shared-IP. For a
shared-IP zone, you must set both the physical and address properties; setting
the default router is optional. The interface specified in the physical
property must be plumbed in the global zone prior to booting the non-global
zone. However, if the interface is not used by the global zone, it should be
configured \fBdown\fR in the global zone, and the default router for the
interface should be specified here.
.sp
For an exclusive-IP zone, the physical property must be set and the address and
default router properties cannot be set.
.RE

.sp
.ne 2
.na
\fB\fBdevice\fR: match\fR
.ad
.sp .6
.RS 4n
Device name to match.
.RE

.sp
.ne 2
.na
\fB\fBrctl\fR: name, value\fR
.ad
.sp .6
.RS 4n
The name and \fIpriv\fR/\fIlimit\fR/\fIaction\fR triple of a resource control.
See \fBprctl\fR(1) and \fBrctladm\fR(1M). The preferred way to set rctl values
is to use the global property name associated with a specific rctl.
.RE

.sp
.ne 2
.na
\fB\fBattr\fR: name, type, value\fR
.ad
.sp .6
.RS 4n
The name, type and value of a generic attribute. The \fBtype\fR must be one of
\fBint\fR, \fBuint\fR, \fBboolean\fR or \fBstring\fR, and the value must be of
that type. \fBuint\fR means unsigned , that is, a non-negative integer.
.RE

.sp
```

```
.ne 2
.na
\fB\fBdataset\fR: name\fR
.ad
.sp .6
.RS 4n
The name of a \fBZFS\fR dataset to be accessed from within the zone. See
\fBzfs\fR(1M).
.RE

.sp
.ne 2
.na
\fBglobal: \fBcpu-shares\fR\fR
.ad
.sp .6
.RS 4n
The number of Fair Share Scheduler (FSS) shares to allocate to this zone. This
property is incompatible with the \fBdedicated-cpu\fR resource. This property
is the preferred way to set the \fBzone.cpu-shares\fR rctl.
.RE

.sp
.ne 2
.na
\fBglobal: \fBmax-lwps\fR\fR
.ad
.sp .6
.RS 4n
The maximum number of LWPs simultaneously available to this zone. This property
is the preferred way to set the \fBzone.max-lwps\fR rctl.
.RE

.sp
.ne 2
.na
\fBglobal: \fBmax-msg-ids\fR\fR
.ad
.sp .6
.RS 4n
The maximum number of message queue IDs allowed for this zone. This property is
the preferred way to set the \fBzone.max-msg-ids\fR rctl.
.RE

.sp
.ne 2
.na
\fBglobal: \fBmax-sem-ids\fR\fR
.ad
.sp .6
.RS 4n
The maximum number of semaphore IDs allowed for this zone. This property is the
preferred way to set the \fBzone.max-sem-ids\fR rctl.
.RE

.sp
.ne 2
.na
\fBglobal: \fBmax-shm-ids\fR\fR
.ad
.sp .6
.RS 4n
The maximum number of shared memory IDs allowed for this zone. This property is
the preferred way to set the \fBzone.max-shm-ids\fR rctl.
.RE
```

```
.sp
.ne 2
.na
\fBglobal: \fBmax-shm-memory\fR\fR
.ad
.sp .6
.RS 4n
The maximum amount of shared memory allowed for this zone. This property is the
preferred way to set the \fBzone.max-shm-memory\fR rctl. A scale (K, M, G, T)
can be applied to the value for this number (for example, 1M is one megabyte).
.RE

.sp
.ne 2
.na
\fBglobal: \fBscheduling-class\fR\fR
.ad
.sp .6
.RS 4n
Specifies the scheduling class used for processes running in a zone. When this
property is not specified, the scheduling class is established as follows:
.RS +4
.TP
.ie t \(bu
.el o
If the \fBcpu-shares\fR property or equivalent rctl is set, the scheduling
class FSS is used.
.RE
.RS +4
.TP
.ie t \(bu
.el o
If neither \fBcpu-shares\fR nor the equivalent rctl is set and the zone's pool
property references a pool that has a default scheduling class, that class is
used.
.RE
.RS +4
.TP
.ie t \(bu
.el o
Under any other conditions, the system default scheduling class is used.
.RE
.RE

.sp
.ne 2
.na
\fB\fBdedicated-cpu\fR: ncpus, importance\fR
.ad
.sp .6
.RS 4n
The number of CPUs that should be assigned for this zone's exclusive use. The
zone will create a pool and processor set when it boots. See \fBpooladm\fR(1M)
and \fBpoolcfg\fR(1M) for more information on resource pools. The \fBncpu\fR
property can specify a single value or a range (for example, 1-4) of
processors. The \fBimportance\fR property is optional; if set, it will specify
the \fBpset.importance\fR value for use by \fBpoold\fR(1M). If this resource is
used, there must be enough free processors to allocate to this zone when it
boots or the zone will not boot. The processors assigned to this zone will not
be available for the use of the global zone or other zones. This resource is
incompatible with both the \fBpool\fR and \fBcpu-shares\fR properties. Only a
single instance of this resource can be added to the zone.
.RE
```

```
.sp
.ne 2
.na
\fB\fBcapped-memory\fR: physical, swap, locked\fR
.ad
.sp .6
.RS 4n
The caps on the memory that can be used by this zone. A scale (K, M, G, T) can
be applied to the value for each of these numbers (for example, 1M is one
megabyte). Each of these properties is optional but at least one property must
be set when adding this resource. Only a single instance of this resource can
be added to the zone. The \fBphysical\fR property sets the \fBmax-rss\fR for
this zone. This will be enforced by \fBrcapd\fR(1M) running in the global zone.
The \fBswap\fR property is the preferred way to set the \fBzone.max-swap\fR
rctl. The \fBlocked\fR property is the preferred way to set the
\fBzone.max-locked-memory\fR rctl.
.RE

.sp
.ne 2
.na
\fB\fBcapped-cpu\fR: ncpus\fR
.ad
.sp .6
.RS 4n
Sets a limit on the amount of CPU time that can be used by a zone. The unit
used translates to the percentage of a single CPU that can be used by all user
threads in a zone, expressed as a fraction (for example, \fB\&.75\fR) or a
mixed number (whole number and fraction, for example, \fB1.25\fR). An
\fBncpu\fR value of \fB1\fR means 100% of a CPU, a value of \fB1.25\fR means
125%, \fB\&.75\fR mean 75%, and so forth. When projects within a capped zone
have their own caps, the minimum value takes precedence.
.sp
The \fBcapped-cpu\fR property is an alias for \fBzone.cpu-cap\fR resource
control and is related to the \fBzone.cpu-cap\fR resource control. See
\fBresource_controls\fR(5).
.RE

.sp
.ne 2
.na
\fB\fBsecurity-flags\fR: lower, default, upper\fR
.ad
.sp .6
.RS 4n
Set the process security flags associated with the zone.  The \fBlower\fR and
\fBupper\fR fields set the limits, the \fBdefault\fR field is set of flags all
zone processes inherit.
.RE

.sp
.ne 2
.na
#endif /* ! codereview */
\fBglobal: \fBfs-allowed\fR\fR
.ad
.sp .6
.RS 4n
A comma-separated list of additional filesystems that may be mounted within
the zone; for example "ufs,pcfs". By default, only hsfs(7fs) and network
filesystems can be mounted. If the first entry in the list is "-" then
that disables all of the default filesystems. If any filesystems are listed
after "-" then only those filesystems can be mounted.

This property does not apply to filesystems mounted into the zone via "add fs"
or "add dataset".
```

```
913 WARNING: allowing filesystem mounts other than the default may allow the zone
914 administrator to compromise the system with a malicious filesystem image, and
915 is not supported.
916 .RE

918 .sp
919 .LP
920 The following table summarizes resources, property-names, and types:
921 .sp
922 .in +2

968 .in -2
969 .sp

971 .sp
972 .LP
973 To further specify things, the breakdown of the complex property "value" of the
974 "rctl" resource type, it consists of three name/value pairs, the names being
975 "priv", "limit" and "action", each of which takes a simple value. The "name"
976 property of an "attr" resource is syntactically restricted in a fashion similar
977 but not identical to zone names: it must begin with an alphanumeric, and can
```

```
978 contain alphanumerics plus the hyphen (\fB-\fR), underscore (\fB_\fR), and dot
979 (\fB\&.\fR) characters. Attribute names beginning with "zone" are reserved for
980 use by the system. Finally, the "autoboot" global property must have a value of
981 "true" or "false".
982 .SS "Using Kernel Statistics to Monitor CPU Caps"
427 .sp
983 .LP
984 Using the kernel statistics (\fBkstat\fR(3KSTAT)) module \fBcaps\fR, the system
985 maintains information for all capped projects and zones. You can access this
986 information by reading kernel statistics (\fBkstat\fR(3KSTAT)), specifying
987 \fBcaps\fR as the \fBkstat\fR module name. The following command displays
988 kernel statistics for all active CPU caps:
989 .sp
990 .in +2
991 .nf
992 # \fBkstat caps::'/cpucaps/'\fR
993 .fi
994 .in -2
995 .sp

997 .sp
998 .LP
999 A \fBkstat\fR(1M) command running in a zone displays only CPU caps relevant for
1000 that zone and for projects in that zone. See \fBEXAMPLES\fR.

.LP
You can use the \fBadd\fR and \fBselect\fR subcommands to select a specific
resource, at which point the scope changes to that resource. The \fBend\fR and
\fBcancel\fR subcommands are used to complete the resource specification, at
which time the scope is reverted back to global. Certain subcommands, such as
\fBadd\fR, \fBremove\fR and \fBset\fR, have different semantics in each scope.
.sp
.LP
\fBzonecfg\fR supports a semicolon-separated list of subcommands. For example:
.sp
```

```
.in +2
.nf
# \fBzonecfg -z myzone "add net; set physical=myvnic; end"\fR
.fi
.in -2
.sp

.sp
.LP
Subcommands which can result in destructive actions or loss of work have an
\fB-F\fR option to force the action. If input is from a terminal device, the
user is prompted when appropriate if such a command is given without the
\fB-F\fR option otherwise, if such a command is given without the \fB-F\fR
option, the action is disallowed, with a diagnostic message written to standard
error.
.sp
.LP
The following subcommands are supported:
.sp
.ne 2
.na
\fB\fBadd\fR \fIresource-type\fR (global scope)\fR
.ad
.br
.na
\fB\fBadd\fR \fIproperty-name property-value\fR (resource scope)\fR
.ad
.sp .6
.RS 4n
In the global scope, begin the specification for a given resource type. The
scope is changed to that resource type.
.sp
In the resource scope, add a property of the given name with the given value.
The syntax for property values varies with different property types. In
general, it is a simple value or a list of simple values enclosed in square
brackets, separated by commas (\fB[foo,bar,baz]\fR). See \fBPROPERTIES\fR.
.RE

.sp
.ne 2
.na
\fB\fBcancel\fR\fR
.ad
.sp .6
.RS 4n
End the resource specification and reset scope to global. Abandons any
partially specified resources. \fBcancel\fR is only applicable in the resource
scope.
.RE

.sp
.ne 2
.na
\fB\fBclear\fR \fIproperty-name\fR\fR
.ad
.sp .6
.RS 4n
Clear the value for the property.
.RE

.sp
.ne 2
.na
\fB\fBcommit\fR\fR
.ad
.sp .6
```

```
.RS 4n
Commit the current configuration from memory to stable storage. The
configuration must be committed to be used by \fBzoneadm\fR. Until the
in-memory configuration is committed, you can remove changes with the
\fBrevert\fR subcommand. The \fBcommit\fR operation is attempted automatically
upon completion of a \fBzonecfg\fR session. Since a configuration must be
correct to be committed, this operation automatically does a verify.
.RE

.sp
.ne 2
.na
\fB\fBcreate [\fR\fB-F\fR\fB] [\fR \fB-a\fR \fIpath\fR |\fB-b\fR \fB|\fR
\fB-t\fR \fItemplate\fR\fB]\fR\fR
.ad
.sp .6
.RS 4n
Create an in-memory configuration for the specified zone. Use \fBcreate\fR to
begin to configure a new zone. See \fBcommit\fR for saving this to stable
storage.
.sp
If you are overwriting an existing configuration, specify the \fB-F\fR option
to force the action. Specify the \fB-t\fR \fItemplate\fR option to create a
configuration identical to \fItemplate\fR, where \fItemplate\fR is the name of
a configured zone.
.sp
Use the \fB-a\fR \fIpath\fR option to facilitate configuring a detached zone on
a new host. The \fIpath\fR parameter is the zonepath location of a detached
zone that has been moved on to this new host. Once the detached zone is
configured, it should be installed using the "\fBzoneadm attach\fR" command
(see \fBzoneadm\fR(1M)). All validation of the new zone happens during the
\fBattach\fR process, not during zone configuration.
.sp
Use the \fB-b\fR option to create a blank configuration. Without arguments,
\fBcreate\fR applies the Sun default settings.
.RE

.sp
.ne 2
.na
\fB\fBdelete [\fR\fB-F\fR\fB]\fR\fR
.ad
.sp .6
.RS 4n
Delete the specified configuration from memory and stable storage. This action
is instantaneous, no commit is necessary. A deleted configuration cannot be
reverted.
.sp
Specify the \fB-F\fR option to force the action.
.RE

.sp
.ne 2
.na
\fB\fBend\fR\fR
.ad
.sp .6
.RS 4n
End the resource specification. This subcommand is only applicable in the
resource scope. \fBzonecfg\fR checks to make sure the current resource is
completely specified. If so, it is added to the in-memory configuration (see
\fBcommit\fR for saving this to stable storage) and the scope reverts to
global. If the specification is incomplete, it issues an appropriate error
message.
.RE
```

```
1305 .sp
1306 .ne 2
1307 .na
1308 \fB\fBexport [\fR\fB-f\fR \fIoutput-file\fR\fB]\fR\fR
1309 .ad
1310 .sp .6
1311 .RS 4n
1312 Print configuration to standard output. Use the \fB-f\fR option to print the
1313 configuration to \fIoutput-file\fR. This option produces output in a form
1314 suitable for use in a command file.
1315 .RE

\fBpoolcfg\fR(1M).
```

```
.LP
\fBExample 5 \fRChanging the Name of a Zone
.sp
.LP
The following example shows how to change the name of an existing zone:

.sp
.in +2
.nf
example# \fBzonecfg -z myzone\fR
zonecfg:myzone> \fBset zonename=myzone2\fR
zonecfg:myzone2> \fBexit\fR
.fi
.in -2
.sp

.LP
\fBExample 6 \fRChanging the Privilege Set of a Zone
.sp
.LP
The following example shows how to change the set of privileges an existing
zone's processes will be limited to the next time the zone is booted. In this
particular case, the privilege set will be the standard safe set of privileges
a zone normally has along with the privilege to change the system date and
time:

.sp
.in +2
.nf
example# \fBzonecfg -z myzone\fR
zonecfg:myzone> \fBset limitpriv="default,sys_time"\fR
zonecfg:myzone2> \fBexit\fR
.fi
.in -2
.sp

.LP
\fBExample 7 \fRSetting the \fBzone.cpu-shares\fR Property for the Global Zone
.sp
.LP
The following command sets the \fBzone.cpu-shares\fR property for the global
zone:

.sp
.in +2
.nf
example# \fBzonecfg -z global\fR
zonecfg:global> \fBset cpu-shares=5\fR
zonecfg:global> \fBexit\fR
.fi
.in -2
.sp

.LP
\fBExample 8 \fRUsing Pattern Matching
.sp
.LP
The following commands illustrate \fBzonecfg\fR support for pattern matching.
In the zone \fBflexlm\fR, enter:

.sp
.in +2
.nf
zonecfg:flexlm> \fBadd device\fR
zonecfg:flexlm:device> \fBset match="/dev/cua/a00[2-5]"\fR
zonecfg:flexlm:device> \fBend\fR
```

```
.fi
.in -2
.sp

.sp
.LP
In the global zone, enter:

.sp
.in +2
.nf
global# \fBls /dev/cua\fR
a     a000  a001  a002  a003  a004  a005  a006  a007  b
.fi
.in -2
.sp

.sp
.LP
In the zone \fBflexlm\fR, enter:

.sp
.in +2
.nf
flexlm# \fBls /dev/cua\fR
a002  a003  a004  a005
.fi
.in -2
.sp

.LP
\fBExample 9 \fRSetting a Cap for a Zone to Three CPUs
.sp
.LP
The following sequence uses the \fBzonecfg\fR command to set the CPU cap for a
zone to three CPUs.

.sp
.in +2
.nf
zonecfg:myzone> \fBadd capped-cpu\fR
zonecfg:myzone>capped-cpu> \fBset ncpus=3\fR
zonecfg:myzone>capped-cpu>capped-cpu> \fBend\fR
.fi
.in -2
.sp

.sp
.LP
The preceding sequence, which uses the capped-cpu property, is equivalent to
the following sequence, which makes use of the \fBzone.cpu-cap\fR resource
control.

.sp
.in +2
.nf
zonecfg:myzone> \fBadd rctl\fR
zonecfg:myzone:rctl> \fBset name=zone.cpu-cap\fR
zonecfg:myzone:rctl> \fBadd value (priv=privileged,limit=300,action=none)\fR
zonecfg:myzone:rctl> \fBend\fR
.fi
.in -2
.sp

.LP
\fBExample 10 \fRUsing \fBkstat\fR to Monitor CPU Caps
```

```
.sp
.LP
The following command displays information about all CPU caps.

.sp
.in +2

.Dt LIBPROC 3LIB
.Os
.Sh NAME
.Nm libproc
.Nd process control library
.Sh SYNOPSIS
.Lb libproc
.In libproc.h
.Sh DESCRIPTION
The
.Nm
library provides consumers a general series of interfaces to inspect
and control both live processes and core files. It is intended for
introspection tools such as debuggers by providing a high-level
interface to the /proc file system
.Pf ( Xr proc 4 ) .
.Pp
The
.Nm
library provides interfaces that focus on:
.Bl -bullet -offset indent
.It
Creating and attaching to live process, core files, and arbitrary ELF
objects.
.It
Interrogating the state of a process or core file.
.It
Manipulating the current state of a process or thread.
.It
Interrogating the state of threads of a process or core file.
.It
Running system calls in the context of another process.
.It
Various utilities for iterating process and core file file descriptors,
mappings, symbols, and more.
.It
Various utilities to support debugging tools.
.El
.Ss Live Processes
The
.Nm
library can be used to manipulate running processes and to create new
```

```
ones. To manipulate an existing process first
.Em grab
it with the
.Em Pgrab
function. A process is generally stopped as a side effect of grabbing
it. Callers must exercise caution, as if they do not use the library
correctly, or they terminate unexpectedly, a process may remain
stopped.
.Pp
Unprivileged users may only grab their own processes. Users with the
privilege
.Sy PRIV_PROC_OWNER
may manipulate processes that they do not own; however, additional
restrictions as described in
.Xr privileges 5
apply.
.Pp
In addition, the
.Fn Pcreate
and
.Fn Pxcreate
functions may be used to create processes which are always controlled by
the library.
.Ss Core Files
The
.Nm
library has the ability to open and interpret core files produced by
processes on the system. Process core dump generation is controlled by
the
.Xr coreadm 1M
command. In addition, the library has the ability to understand and
interpret core dumps generated by Linux kernel and can provide a subset
of its functionality on such core files, provided the original binary is
also present.
.Pp
Not all functions in the
.Nm
library are valid for core files. In general, none of the commands
which manipulate the current state of a process or thread or that try
to force system calls on a victim process will work. Furthermore
several of the information and iteration interfaces are limited based
on the data that is available in the core file. For example, if the
core file is of a process that omits the frame pointer, the ability to
iterate the stack will be limited.
.Pp
Use the
.Fn Pgrab_core
or
.Fn Pfgrab_core
function to open a core file. Use the
.Fn Pgrab_file
function to open an ELF object file.
This is useful for obtaining information stored in ELF headers and
sections.
.Ss Debug Information
Many of the operations in the library rely on debug information being
present in a process and its associated libraries. The library
leverages symbol table information, CTF data
.Pf ( Xr CTF 4 )
sections, and frame unwinding information based on the use of an ABI
defined frame pointer, eg.
.Sy %ebp
and
.Sy %rbp
on x86 systems.
.Pp
```

```
123 Some software providers strip programs of this information or build
124 their executables such that the information will not be present in a
125 core dump. To deal with this fact, the library is able to consume
126 information that is not present in the core file or the running
127 process. It can both consume it from the underlying executable and it
128 also supports finding it from related ELF objects that are linked to
129 it via the
130 .Sy .gnu_debuglink
131 and the
132 .Sy .note.gnu.build-id
133 ELF sections.
134 .Ss Iteration Interfaces
135 The
136 .Nm
137 library provides the ability to iterate over the following aspects of a
138 process or core file:
139 .Bl -bullet -offset indent
140 .It
141 Active threads
142 .It
143 Active and zombie threads
144 .It
145 All non-system processes
146 .It
147 All process mappings
148 .It
149 All objects in a process
150 .It
151 The environment
152 .It
153 The symbol table
154 .It
155 Stack frames
156 .It
157 File Descriptors
158 .El
159 .Ss System Call Injection
160 The
161 .Nm
162 library allows the caller to force system calls to be executed in the
163 context of the running process. This can be used both as a tool for
164 introspection, allowing one to get information outside its current
165 context as well as performing modifications to a process.
166 .Pp
167 These functions run in the context of the calling process. This is
168 often an easier way of getting non-exported information about a
169 process from the system. For example, the
170 .Xr pfiles 1
171 command uses this interface to get more detailed information about a
172 process’s open file descriptors, which it would not have access to
173 otherwise.
174 .Sh INTERFACES
175 The shared object
176 .Sy libproc.so.1
177 provides the public interfaces defined below. See
178 .Xr Intro 3
179 for additional information on shared object interfaces. Functions are
180 organized into categories that describe their purpose. Individual
181 functions are documented in their own manual pages.
182 .Ss Creation, Grabbing, and Releasing
183 The following routines are related to creating library handles,
184 grabbing cores, processes, and threads, and releasing those resources.
185 .Bl -column -offset indent ".Sy Pmapping_iter_resolved" ".Sy Psymbol_iter_by_add
186 .It Sy Lfree Ta Sy Lgrab
187 .It Sy Lgrab_error Ta Sy Pcreate
188 .It Sy Pcreate_agent Ta Sy Pcreate_callback
```

```
189 .It Sy Pcreate_error Ta Sy Pdestroy_agent
190 .It Sy Pfgrab_core Ta Sy Pfree
191 .It Sy Pgrab Ta Sy Pgrab_core

.El
.Ss x86 Specific Routines
The following routines are specific to the x86, 32-bit and 64-bit,
versions of the
.Nm
library.
.Bl -column -offset indent ".Sy Pmapping_iter_resolved" ".Sy Psymbol_iter_by_add
.It Sy Pldt Ta Sy proc_get_ldt
.El
.Ss SPARC specific Routines
The following functions are specific to the SPARC, 32-bit and 64-bit,
versions of the
.Nm
library.
.Bl -column -offset indent ".Sy Pmapping_iter_resolved" ".Sy Psymbol_iter_by_add
.It Sy Plwp_getgwindows Ta Sy Plwp_getxregs
.It Sy Plwp_setxregs Ta Sy ""
.El
.Pp
The following functions are specific to the 64-bit SPARC version of the
.Nm
library.
.Bl -column -offset indent ".Sy Pmapping_iter_resolved" ".Sy Psymbol_iter_by_add
.It Sy Plwp_getasrs Ta Sy Plwp_setasrs
.El
.Sh PROCESS STATES
Every process handle that exists in
.Nm
has a state. In some cases, such as for core files, these states are
static. In other cases, such as handles that correspond to a
running process or a created process, these states are dynamic and
change based on actions taken in the library. The state can be obtained
with the
.Xr Pstate 3PROC
function.
.Pp
The various states are:
.Bl -tag -width Dv -offset indent
.It Dv PS_RUN
An actively running process. This may be a process that was obtained
by creating it with functions such as
.Xr Pcreate 3PROC
or by grabbing an existing process such as
.Xr Pgrab 3PROC .
.It Dv PS_STOP
An active process that is no longer executing. A process may stop for
many reasons such as an explicit stop request (through
.Xr pstop 1
for example) or if a tracing event is hit.
.Pp
The reason a process is stopped may be obtained through the thread's
.Sy lwpstatus_t
structure read directly from /proc or obtained through the
.Xr Lstatus 3PROC
```

```
371 function.
372 .It Dv PS_LOST
373 Control over the process has been lost. This may happen when the
374 process executes a new image requiring a different set of privileges.
375 To resume control call
376 .Xr Preopen 3PROC . For more information on losing control of a process,
377 see
378 .Xr proc 4 .
379 .It DV PS_UNDEAD
380 A zombie process. It has terminated, but it has not been cleaned up
381 yet by its parent. For more on the conditions of becoming a zombie,
382 see
383 .Xr exec 2 .
384 .It DV_PS_DEAD
385 Processes in this state are always core files. See the earlier section
386 .Sx Core Files
387 for more information on working with core files.
388 .It Dv PS_IDLE
389 A process that has never been run. This is always the case for handles
390 that refer to files as the files cannot be executed. Those process
391 handles are obtained through calling
392 .Xr Pgrab_file 3PROC .
393 .El
394 .Pp
395 Many functions relating to tracing processes, for example
396 .Xr Psignal 3PROC ,
397 .Xr Psetsignal 3PROC ,
398 .Xr Psetfault 3PROC ,
399 .Xr Psetentry 3PROC ,
400 and others, mention that they only act upon
401 .Em Active Processes .
402 This specifically refers to processes whose state are in
403 .Dv PS_RUN
404 and
405 .Dv PS_STOP .
406 Process handles in the other states have no notion of settable tracing
407 flags, though core files
408 .Pf ( type Dv PS_DEAD ) ,
409 =======
410 may have a read-only snapshot of their tracing settings available.
411 .Sh TYPES
412 The
413 .Nm
414 library uses many types that come from the /proc file system
415 .Pf ( Xr proc 4 )
416 and the ELF format
417 .Pf ( Xr elf 3ELF ) .
418 However, it also defines the following types:
419 .Pp
420 .Sy struct ps_prochandle
421 .Pp
422 The
423 .Sy struct ps_prochandle
424 is an opaque handle to the library and the core element of control for a
425 process. Consumers obtain pointers to a handle through the use of the
426 .Fn Pcreate ,
427 .Fn Pgrab ,
428 and related functions. When a caller is done with a handle, then it
429 should call one of the
430 .Fn Pfree
431 and
432 .Fn Prelease
433 functions to relinquish the handle, release associated resources, and
434 potentially set the process to run again.
435 .Pp
436 .Sy struct ps_lwphandle
```

```
437 .Pp
438 The
439 .Sy struct ps_lwphandle
440 is analogous to the
441 .Sy struct ps_prochandle ,
442 but it represents the control of an individual thread, rather than a
443 process. Consumers obtain pointers to a handle through the
444 .Fn Lgrab
445 function and relinquish it with the
446 .Fn Lfree
447 function.
448 .Pp
449 .Sy core_content_t
450 .Pp
451 The
452 .Sy core_content_t
453 is a value which describes the various content types of core files.
454 These are used in functions such as
455 .Xr Pcontent 3PROC
456 and
457 .Xr Pgcore 3PROC
458 to describe and control the types of content that get included. Various
459 content types may be included together through a bitwise-inclusive-OR.
460 The default system core contents are controlled with the
461 .Xr coreadm 1M
462 tool. The following table lists the current set of core contents in the
463 system, though the set may increase over time. The string after the
464 macro is the human readable string that corresponds with the constant
465 and is used by
466 .Xr coreadm 1M ,
467 .Xr proc_content2str 3PROC ,
468 and
469 .Xr proc_str2content 3PROC .
470 .Bl -tag -offset indent -width indent
471 .It Dv CC_CONTENT_STACK ("stack")
472 The contents include the process stack. Note, this only covers the main
473 thread's stack. The stack of other threads is covered by
474 .Dv CC_CONTENT_ANON .
475 .It Dv CC_CONTENT_HEAP ("heap")
476 The contents include the process heap.
477 .It Dv CC_CONTENT_SHFILE ("shfile")
478 The contents include shared mappings that are backed by files (e.g.
479 mapped through
480 .Xr mmap 2
481 with the
482 .Dv MAP_SHARED
483 flag).
484 .It Dv CC_CONTENT_SHANNON ("shannon")
485 The contents include shared mappings that are backed by anonymous memory
486 (e.g. mapped through
487 .Xr mmap 2
488 with the
489 .Dv MAP_SHARED
490 and
491 .Dv MAP_ANON
492 flags).
493 .It Dv CC_CONTENT_RODATA ("rodata")
494 The contents include private read-only file mappings, such as shared
495 library text.
496 .It Dv CC_CONTENT_ANON ("anon")
497 The contents include private anonymous mappings. This includes the
498 stacks of threads which are not the main thread.
499 .It Dv CC_CONTENT_SHM ("shm")
500 The contents include system V shared memory.
501 .It Dv CC_CONTENT_ISM ("ism")
502 The contents include ISM (intimate shared memory) mappings.
```

```
.It Dv CC_CONTENT_DISM ("dism")
The contents include DISM (dynamic shared memory) mappings.
.It Dv CC_CONTENT_CTF ("ctf")
The contents include
.Xr ctf 4
(Compact C Type Format) information. Note, not all objects in the
process may have CTF information available.
.It Dv CC_CONTENT_SYMTAB ("symtab")
The contents include the symbol table. Note, not all objects in the
process may have a symbol table available.
.It Dv CC_CONTENT_ALL ("all")
This value indicates that all of the above content values are present.
Note that additional values may be added in the future, in which case
the value of the symbol will be updated to include them. Comparisons
with
.Dv CC_CONTENT_ALL
should validate all the expected bits are set by an expression such as
.Li (c & CC_CONTENT_ALL) == CC_CONTENT_ALL .
.It Dv CC_CONTENT_NONE ("none")
This value indicates that there is no content present.
.It Dv CC_CONTENT_DEFAULT ("default")
The content includes the following set of default values:
.Dv CC_CONTENT_STACK ,
.Dv CC_CONTENT_HEAP ,
.Dv CC_CONTENT_ISM ,
.Dv CC_CONTENT_DISM ,
.Dv CC_CONTENT_SHM ,
.Dv CC_CONTENT_SHANON ,
.Dv CC_CONTENT_TEXT ,
.Dv CC_CONTENT_DATA ,
.Dv CC_CONTENT_RODATA ,
.Dv CC_CONTENT_ANON ,
.Dv CC_CONTENT_CTF ,
and
.Dv CC_CONTENT_SYMTAB.
Note that the default may change. Comparisons with CC_CONTENT_DEFAULT
should validate that all of the expected bits are set with an expression
such as
.Li (c\ &\ CC_CONTENT_DEFAULT)\ ==\ CC_CONTENT_DEFAULT.
.It Dv CC_CONTENT_INVALID
This indicates that the contents are invalid.
.El
.Pp
.Sy prfdinfo_t
.Pp
The
.Sy prfdinfo_t
structure is used with the
.Fn Pfdinfo_iter
function which describes information about a file descriptor. The
structure is defined as follows:
.Bd -literal
typedef struct prfdinfo {
        int             pr_fd;
        mode_t          pr_mode;
        uid_t           pr_uid;
        gid_t           pr_gid;
        major_t         pr_major;       /* think stat.st_dev */
        minor_t         pr_minor;
        major_t         pr_rmajor;      /* think stat.st_rdev */
        minor_t         pr_rminor;
        ino64_t         pr_ino;
        off64_t         pr_offset;
        off64_t         pr_size;
        int             pr_fileflags;   /* fcntl(F_GETXFL), etc */
        int             pr_fdflags;     /* fcntl(F_GETFD), etc. */
```

```
        char            pr_path[MAXPATHLEN];
} prfdinfo_t;
_____unchanged_portion_omitted_
.Ed
.Pp
The member
.Sy prs_object
points to a string that contains the name of the object file, if known,
that the symbol comes from. The member
.Sy prs_name
points to the name of the symbol, if known. This may be unknown due to a
stripped binary that contains no symbol table. The member
.Sy prs_lmid
indicates the link map identifier that the symbol was found on. For more
information on link map identifiers refer to the
.Em Linker and Libraries Guide
and
.Xr dlopen 3C .
.Pp
The members
.Sy prs_id
and
.Sy prs_table
can be used to determine both the symbol table that the entry came from
and which entry in the table it corresponds to. If the value of
.Sy prs_table
is
.Dv PR_SYMTAB
then it came from the ELF standard symbol table. However, if it is instead
.Dv PR_DYNSYM ,
then that indicates that it comes from the process's dynamic section.
.Pp
.Sy proc_lwp_f
.Pp
The
.Sy proc_lwp_f
is a function pointer type that is used with the
.Fn Plwp_iter
function. It is defined as
.Sy typedef
.Ft int
.Fo proc_lwp_f
.Fa "void *"
.Fa "const lwpstatus_t *"
.Fc .
The first argument is a pointer to an argument that the user specifies,
while the second has the thread's status information and is defined in
.Xr proc 4 .
For additional information on using this type, see
.Xr Plwp_iter 3PROC .
.Pp
.Sy proc_lwp_all_f
.Pp
The
.Sy proc_lwp_all_f
is a function pointer type that is used with the
.Fn Plwp_iter_all
function. It is defined as
.Sy typedef
.Ft int
.Fo proc_lwp_all_f
.Fa "void *"
.Fa "const lwpstatus_t *"
.Fa "const lwpsinfo_t *"
.Fc .
The first argument is a pointer to an argument that the user specifies.
```

```
718 The second and third arguments contain the thread’s status and
719 thread-specific
720 .Xr ps 1
721 information respectively. Both structures are defined in
722 .Xr proc 4 .
723 For additional information on using this type, see
724 .Xr Plwp_iter_all 3PROC .
725 .Pp
726 .Sy proc_walk_f
727 .Pp
728 The
729 .Sy proc_walk_f
730 is a function pointer type that is used with the
731 .Fn proc_walk
732 function. It is defined as
733 .Sy typedef
734 .Ft int
735 .Fo proc_walk_f
736 .Fa "psinfo_t *"
737 .Fa "lwpsinfo_t *"
738 .Fa "void *"
739 .Fc .
740 The first argument contains the process
741 .Xr ps 1
742 information and the second argument contains the representative thread’s
743 .Xr ps 1
744 information. Both structures are defined in
745 .Xr proc 4 .
746 The final argument is a pointer to an argument that the user specifies.
747 For more information on using this, see
748 .Xr proc_walk 3PROC .
749 .Pp
750 .Sy proc_map_f
751 .Pp
752 The
753 .Sy proc_map_f
754 is a function pointer type that is used with the
755 .Fn Pmapping_iter ,
756 .Fn Pmapping_iter_resolved ,
757 .Fn Pobject_iter ,
758 and
759 .Fn Pobject_iter_resolved
760 functions. It is defined as
761 .Sy typedef
762 .Ft int
763 .Fo proc_map_f
764 .Fa "void *"
765 .Fa "const prmap_t *"
766 .Fa "const char *"
767 .Fc .
768 The first argument is a pointer to an argument that the user specifies.
769 The second argument is describes the mapping information and is defined
770 in
771 .Xr proc 4 .
772 The final argument contains the name of the mapping or object file in
773 question. For additional information on using this type, see
774 .Xr Pmapping_iter 3PROC .
775 .Pp
776 .Sy proc_env_f
777 .Pp
778 The
779 .Sy proc_env_f
780 is a function pointer type that is used with the
781 .Fn Penv_iter
782 function. It is defined as
783 .Sy typedef
```

```
784 .Ft int
785 .Fo proc_env_f
786 .Fa "void *"
787 .Fa "struct ps_prochandle *"
788 .Fa "uintptr_t"
789 .Fa "const char *"
790 .Fc .
791 The first argument is a pointer to an argument that the user specifies.
792 The second argument is a pointer to the
793 .Sy struct ps_prochandle
794 that the callback was passed to. The third argument is the address of
795 the environment variable in the process. The fourth argument is the
796 environment variable. Values in the environment follow the convention of
797 the form
798 .Em variable=value .
799 For more information on environment variables see
800 .Xr exec 2
801 and
802 .Xr environ 5 .
803 For additional information on using this type, see
804 .Xr Penv_iter 3PROC .
805 .Pp
806 .Sy proc_sym_f
807 .Pp
808 The
809 .Sy proc_sym_f
810 is a function pointer type that is used with the
811 .Fn Psmbol_iter ,
812 .Fn Psymbol_iter_by_addr ,
813 .Fn Psymbol_iter_by_name ,
814 and
815 .Fn Psymbol_iter_by_lmid
816 functions. It is defined as
817 .Sy typedef
818 .Ft int
819 .Fo proc_sym_f
820 .Fa "void *"
821 .Fa "const GElf_Sym *"
822 .Fa "const char *"
823 .Fc .
824 The first argument is a pointer to an argument that the user supplies.
825 The second argument is a pointer to the ELF symbol information in a
826 32-bit and 64-bit neutral form. See
827 .Xr elf 3ELF
828 and
829 .Xr gelf 3ELF
830 for more information on it. The final argument points to a character
831 string that has the name of the symbol. For additional information on
832 using this type, see
833 .Xr Psymbol_iter 3PROC ,
834 .Xr Psymbol_iter_by_addr 3PROC ,
835 .Xr Psymbol_iter_by_name 3PROC ,
836 and
837 .Xr Psymbol_iter_by_lmid 3PROC .
838 .Pp
839 .Sy proc_xsym_f
840 .Pp
841 The
842 .Sy proc_xsym_f
843 is a function pointer type that is used with the
844 .Fn Pxsymbol_iter
845 function. It is defined as
846 .Sy typedef
847 .Ft int
848 .Fo proc_xsym_f
849 .Fa "void *"
```

```
.Fa "const GElf_Sym *"
.Fa "const char *"
.Fa "const prsyminfo_t *"
.Fc .
The first three arguments are identical to those of
.Sy proc_sym_f .
The final argument contains additional information about the symbol
itself. The members of the
.Sy prsyminfo_t
are defined earlier in this section. For additional information on using
this type, see
.Xr Pxsymbol_iter 3PROC .
.Pp
.Sy proc_stack_f
.Pp
The
.Sy proc_stack_f
is a function pointer type that is used with the
.Fn Pstack_iter
function. It is defined as
.Sy typedef
.Ft int
.Fo proc_stack_f
.Fa "void *"
.Fa "prgregset_t"
.Fa "uint_t"
.Fa "const long *"
.Fc .
The first argument is a pointer to an argument that the user specifies.
The second argument's contents are platform specific. The registers that
contain stack information, usually the stack pointer and frame pointer,
will be filled in to point to an entry. The
.Sy prgregset_t
is defined in
.Xr proc 4 .
.Pp
The third argument contains the number of arguments to the current stack
frame and the fourth argument contains an array of addresses that
correspond to the arguments to that stack function. The value of the
third argument dictates the number of entries in the fourth argument.
For additional information on using this type, see
.Xr Pstack_iter 3PROC .
.Pp
.Sy proc_fdinfo_f
.Pp
The
.Sy proc_fdinfo_f
is a function pointer type that is used with the
.Fn Pfdinfo_iter
function. It is defined as
.Sy typedef
.Ft int
.Fo proc_fdinfo_f
.Fa "void *"
.Fa "prfdinfo_t *"
.Fc .
The first argument is a pointer to an argument that the user specifies.
The second argument contains information about an open file descriptor.
The members of the
.Sy prfdinfo_t
are defined earlier in this section. For additional information on using
this type, see
.Xr Pfdinfo_iter 3PROC .
.Sh PROGRAMMING NOTES
When working with live processes, whether from the
.Xr Pgrab
```

```
or
.Xr Pcreate
family of functions, there are some additional considerations.
Importantly, if a process calls any of the
.Xr exec 2
suite of functions, much of the state information that is obtained,
particularly that about mappings in the process will be invalid. Callers
must ensure that they call
.Xr Preset_maps 3PROC
when they hold a process handle across an exec. In addition, users of
the library should familiarize themselves with the
.Sy PROGRAMMING NOTES
section of the
.Xr proc 4
manual page, which discusses issues of privileges and security.
.Sh DEBUGGING
The library provides a means for obtaining additional debugging
information. The output itself is not part of the
.Nm
library's stable interface. Setting the environment variable
.Ev LIBPROC_DEBUG
to some value will print information to standard error. For example,
.Ev LIBPROC_DEUBG Ns = Ns Em please .
.Sh LOCKING
Most functions operate on a handle to a process in the form of a
.Vt "struct ps_prochandle *" .
Unless otherwise indicated, the library does not provide any
synchronization for different routines that are operating on the
.Sy same
.Nm
library handle. It is up to the caller to ensure that only a single
thread is using a handle at any given time. Multiple threads may call
.Nm
library routines at the same time as long as each thread is using a
different handle.
.Pp
Each individual function notes its
.Sy MT-Level
section. The MT-Level of a routine that matches the above description
will refer to this manual page. If it does not, then it refers to the
standard attributes in
.Xr attributes 5 .
.Sh INTERFACE STABILITY
.Sy Uncommitted
.Pp
While the library is considered an uncommitted interface, and is still
evolving, changes that break compatibility have been uncommon and this
trend is expected to continue. It is documented to allow consumers,
whether part of illumos or outside of it, to understand the libarary and
make use of it with the understanding that changes may occur which break
both source and binary compatibility.

.Dt PSECFLAGS 3PROC
.Os
.Sh NAME
.Nm Psecflags ,
.Nm Psecflags_free
.Nd get and free process security flags
.Sh SYNOPSIS
.Lb libproc
.In libproc.h
.Ft int
.Fo Psecflags
.Fa "struct ps_prochandle *P"
.Fa "prsecflags_t **psf"
.Fc
.Ft void
.Fo Psecflags_free
.Fa "struct ps_prochandle *P"
.Fa "prsecflags_t *psf"
.Fc
.Sh DESCRIPTION
The
.Fn Psecflags
function obtains the security flags of the process handle
.Fa P .
The security flags structure will be dynamically allocated and a pointer to it
will be placed in
.Fa psf .
It must be released with a call to
.Fn Psecflags_free .
The definition of the
.Sy prsecflags_t
structure is documented in
.Xr proc 4 .
.Pp
The
.Fn Psecflags_free
function releases the storage in
.Fa psf
that was allocated as a result of calling
.Fn Psecflags .
.Sh RETURN VALUES
Upon successful completion, the
.Fn Psecflags
```

```
function returns
.Sy 0
and
.Fa psf
is updated with a pointer to the allocated security flags. Otherwise,
.Sy -1
is returned and
.Fa psf
is not updated.
.Sh INTERFACE STABILITY
.Sy Uncommitted
.Sh MT-LEVEL
See
.Sy LOCKING
in
.Xr libproc 3LIB .
.Sh SEE ALSO
.Xr libproc 3LIB ,
.Xr proc 4 ,
.Xr security-flags 5
#endif /* ! codereview */

   9 .TH CORE 4 "Jun 6, 2016"
   9 .TH CORE 4 "Mar 31, 2013"
  10 .SH NAME
  11 core \- process core file
  12 .SH DESCRIPTION
  13 .sp
  13 .LP
  14 The operating system writes out a core file for a process when the process is
  15 terminated due to receiving certain signals. A core file is a disk copy of the
  16 contents of the process address space at the time the process received the
  17 signal, along with additional information about the state of the process. This
  18 information can be consumed by a debugger. Core files can also be generated by
  19 applying the \fBgcore\fR(1) utility to a running process.
  20 .sp
  21 .LP
  22 Typically, core files are produced following abnormal termination of a process
  23 resulting from a bug in the corresponding application. Whatever the cause, the
  24 core file itself provides invaluable information to the programmer or support
  25 engineer to aid in diagnosing the problem. The core file can be inspected using
  26 a debugger such as \fBdbx\fR(1) or \fBmdb\fR(1) or by applying one of the
  27 \fBproc\fR(1) tools.
  28 .sp
  29 .LP
  30 The operating system attempts to create up to two core files for each
  31 abnormally terminating process, using a global core file name pattern and a
  32 per-process core file name pattern. These patterns are expanded to determine
  33 the pathname of the resulting core files, and can be configured by
  34 \fBcoreadm\fR(1M). By default, the global core file pattern is disabled and not
  35 used, and the per-process core file pattern is set to \fBcore\fR. Therefore, by
  36 default, the operating system attempts to create a core file named \fBcore\fR
  37 in the process's current working directory.
  38 .sp
  39 .LP
  40 A process terminates and produces a core file whenever it receives one of the
  41 signals whose default disposition is to cause a core dump. The list of signals
  42 that result in generating a core file is shown in \fBsignal.h\fR(3HEAD).
  43 Therefore, a process might not produce a core file if it has blocked or
  44 modified the behavior of the corresponding signal. Additionally, no core dump
  45 can be created under the following conditions:
  46 .RS +4
  47 .TP
  48 .ie t \(bu
  49 .el o
  50 If normal file and directory access permissions prevent the creation or
  51 modification of the per-process core file pathname by the current process user
  52 and group ID. This test does not apply to the global core file pathname
  53 because, regardless of the UID of the process dumping core, the attempt to
  54 write the global core file is made as the superuser.
  55 .RE
```

```
  56 .RS +4
  57 .TP
  58 .ie t \(bu
  59 .el o
  60 Core files owned by the user \fBnobody\fR will not be produced. For example,
  61 core files generated for the superuser on an NFS directory are owned by
  62 \fBnobody\fR and are, therefore, not written.
  63 .RE
  64 .RS +4
  65 .TP
  66 .ie t \(bu
  67 .el o
  68 If the core file pattern expands to a pathname that contains intermediate
  69 directory components that do not exist. For example, if the global pattern is
  70 set to \fB/var/core/%n/core.%p\fR, and no directory \fB/var/core/'uname -n'\fR
  71 has been created, no global core files are produced.
  72 .RE
  73 .RS +4
  74 .TP
  75 .ie t \(bu
  76 .el o
  77 If the destination directory is part of a filesystem that is mounted read-only.
  78 .RE
  79 .RS +4
  80 .TP
  81 .ie t \(bu
  82 .el o
  83 If the resource limit \fBRLIMIT_CORE\fR has been set to \fB0\fR for the
  84 process, no per-process core file is produced. Refer to \fBsetrlimit\fR(2) and
  85 \fBulimit\fR(1) for more information on resource limits.
  86 .RE
  87 .RS +4
  88 .TP
  89 .ie t \(bu
  90 .el o
  91 If the core file name already exists in the destination directory and is not a
  92 regular file (that is, is a symlink, block or character special-file, and so
  93 forth).
  94 .RE
  95 .RS +4
  96 .TP
  97 .ie t \(bu
  98 .el o
  99 If the kernel cannot open the destination file \fBO_EXCL\fR, which can occur if
 100 same file is being created by another process simultaneously.
 101 .RE
 102 .RS +4
 103 .TP
 104 .ie t \(bu
 105 .el o
 106 If the process's effective user ID is different from its real user ID or if its
 107 effective group ID is different from its real group ID. Similarly, set-user-ID
 108 and set-group-ID programs do not produce core files as this could potentially
 109 compromise system security. These processes can be explicitly granted
 110 permission to produce core files using \fBcoreadm\fR(1M), at the risk of
 111 exposing secure information.
 112 .RE
 113 .sp
 114 .LP
 115 The core file contains all the process information pertinent to debugging:
 116 contents of hardware registers, process status, and process data. The format of
 117 a core file is object file specific.
 118 .sp
 119 .LP
 120 For ELF executable programs (see \fBa.out\fR(4)), the core file generated is
 121 also an ELF file, containing ELF program and file headers. The \fBe_type\fR
```

field in the file header has type \fBET_CORE\fR. The program header contains an entry for every segment that was part of the process address space, including shared library segments. The contents of the mappings specified by \fBcoreadm\fR(1M) are also part of the core image. Each program header has its \fBp_memsz\fR field set to the size of the mapping. The program headers that represent mappings whose data is included in the core file have their \fBp_filesz\fR field set the same as \fBp_memsz\fR, otherwise \fBp_filesz\fR is \fBzero\fR.

.sp
.LP
A mapping’s data can be excluded due to the core file content settings (see \fBcoreadm\fR(1M)), due to a failure, or due to a signal received after core dump initiation but before its completion. If the data is excluded because of a failure, the program header entry will have the \fBPF_SUNW_FAILURE\fR flag set in its \fBp_flags\fR field; if the data is excluded because of a signal, the segment’s \fBp_flags\fR field will have the \fBPF_SUNW_KILLED\fR flag set.

.sp
.LP
The program headers of an \fBELF\fR core file also contain entries for two \fBNOTE\fR segments, each containing several note entries as described below. The note entry header and core file note type (\fBn_type\fR) definitions are contained in <\fBsys/elf.h\fR>. The first \fBNOTE\fR segment exists for binary compatibility with old programs that deal with core files. It contains structures defined in <\fBsys/old_procfs.h\fR>. New programs should recognize and skip this \fBNOTE\fR segment, advancing instead to the new \fBNOTE\fR segment. The old \fBNOTE\fR segment is deleted from core files in a future release.

.sp
.LP
The old \fBNOTE\fR segment contains the following entries. Each has entry name \fB"CORE"\fR and presents the contents of a system structure:

.sp
.ne 2
.na
\fB\fBprpsinfo_t\fR\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_PRPSINFO\fR. This entry contains information of interest to the \fBps\fR(1) command, such as process status, \fBCPU\fR usage, \fBnice\fR value, controlling terminal, user-ID, process-ID, the name of the executable, and so forth. The \fBprpsinfo_t\fR structure is defined in <\fBsys/old_procfs.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBchar\fR array\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_PLATFORM\fR. This entry contains a string describing the specific model of the hardware platform on which this core file was created. This information is the same as provided by \fBsysinfo\fR(2) when invoked with the command \fBSI_PLATFORM\fR.
.RE

.sp
.ne 2
.na
\fB\fBauxv_t\fR array\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_AUXV\fR. This entry contains the array of \fBauxv_t\fR structures that was passed by the operating system as startup information to

the dynamic linker. Auxiliary vector information is defined in <\fBsys/auxv.h\fR>.
.RE

.sp
.LP
Following these entries, for each active (non-zombie) light-weight process (LWP) in the process, the old \fBNOTE\fR segment contains an entry with a \fBprstatus_t\fR structure, plus other optionally-present entries describing the LWP, as follows:

.sp
.ne 2
.na
\fB\fBprstatus_t\fR\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_PRSTATUS\fR. This structure contains things of interest to a debugger from the operating system, such as the general registers, signal dispositions, state, reason for stopping, process-ID, and so forth. The \fBprstatus_t\fR structure is defined in <\fBsys/old_procfs.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBprfpregset_t\fR\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_PRFPREG\fR. This entry is present only if the \fBLWP\fR used the floating-point hardware. It contains the floating-point registers. The \fBprfpregset_t\fR structure is defined in <\fBsys/procfs_isa.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBgwindows_t\fR\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_GWINDOWS\fR. This entry is present only on a SPARC machine and only if the system was unable to flush all of the register windows to the stack. It contains all of the unspilled register windows. The \fBgwindows_t\fR structure is defined in <\fBsys/regset.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBprxregset_t\fR\fR
.ad
.RS 16n
\fBn_type\fR: \fBNT_PRXREG\fR. This entry is present only if the machine has extra register state associated with it. It contains the extra register state. The \fBprxregset_t\fR structure is defined in <\fBsys/procfs_isa.h\fR>.
.RE

.sp
.LP
The new \fBNOTE\fR segment contains the following entries. Each has entry name "\fBCORE\fR" and presents the contents of a system structure:

.sp
.ne 2
.na
\fB\fBpsinfo_t\fR\fR
.ad
.RS 20n

\fBn_type\fR: \fBNT_PSINFO\fR. This structure contains information of interest to the \fBps\fR(1) command, such as process status, \fBCPU\fR usage, \fBnice\fR value, controlling terminal, user-ID, process-ID, the name of the executable, and so forth. The \fBpsinfo_t\fR structure is defined in <\fBsys/procfs.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBpstatus_t\fR\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_PSTATUS\fR. This structure contains things of interest to a debugger from the operating system, such as pending signals, state, process-ID, and so forth. The \fBpstatus_t\fR structure is defined in <\fBsys/procfs.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBchar\fR array\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_PLATFORM\fR. This entry contains a string describing the specific model of the hardware platform on which this core file was created. This information is the same as provided by \fBsysinfo\fR(2) when invoked with the command \fBSI_PLATFORM\fR.
.RE

.sp
.ne 2
.na
\fB\fBauxv_t\fR array\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_AUXV\fR. This entry contains the array of \fBauxv_t\fR structures that was passed by the operating system as startup information to the dynamic linker. Auxiliary vector information is defined in <\fBsys/auxv.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBstruct utsname\fR\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_UTSNAME\fR. This structure contains the system information that would have been returned to the process if it had performed a \fBuname\fR(2) system call prior to dumping core. The \fButsname\fR structure is defined in <\fBsys/utsname.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBprcred_t\fR\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_PRCRED\fR. This structure contains the process credentials, including the real, saved, and effective user and group IDs. The \fBprcred_t\fR structure is defined in <\fBsys/procfs.h\fR>. Following the structure is an optional array of supplementary group IDs. The total number of supplementary group IDs is given by the \fBpr_ngroups\fR member of the \fBprcred_t\fR structure, and the structure includes space for one supplementary group. If \fBpr_ngroups\fR is greater than 1, there is \fBpr_ngroups - 1\fR \fBgid_t\fR

items following the structure; otherwise, there is no additional data.
.RE

.sp
.ne 2
.na
\fB\fBchar array\fR\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_ZONENAME\fR. This entry contains a string which describes the name of the zone in which the process was running. See \fBzones\fR(5). The information is the same as provided by \fBgetzonenamebyid\fR(3C) when invoked with the numerical ID returned by \fBgetzoneid\fR(3C).
.RE

.sp
.ne 2
.na
\fB\fBprfdinfo_t\fR\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_FDINFO\fR. This structure contains information about any open file descriptors, including the path, flags, and \fBstat\fR(2) information. The \fBprfdinfo_t\fR structure is defined in <\fBsys/procfs.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBstruct ssd\fR array\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_LDT\fR. This entry is present only on an 32-bit x86 machine and only if the process has set up a Local Descriptor Table (LDT). It contains an array of structures of type \fBstruct ssd\fR, each of which was typically used to set up the \fB%gs\fR segment register to be used to fetch the address of the current thread information structure in a multithreaded process. The \fBssd\fR structure is defined in <\fBsys/sysi86.h\fR>.
.RE

.sp
.ne 2
.na
\fB\fBcore_content_t\fR\fR
.ad
.RS 20n
\fBn_type\fR: \fBNT_CONTENT\fR. This optional entry indicates which parts of the process image are specified to be included in the core file. See \fBcoreadm\fR(1M).
.RE

.sp
.LP
Following these entries, for each active and zombie \fBLWP\fR in the process, the new \fBNOTE\fR segment contains an entry with an \fBlwpsinfo_t\fR structure plus, for a non-zombie LWP, an entry with an \fBlwpstatus_t\fR structure, plus other optionally-present entries describing the LWP, as follows. A zombie LWP is a non-detached LWP that has terminated but has not yet been reaped by another LWP in the same process.
.sp
.ne 2
.na
\fB\fBlwpsinfo_t\fR\fR
.ad
.RS 15n

```
386 \fBn_type\fR: \fBNT_LWPSINFO\fR. This structure contains information of
387 interest to the \fBps\fR(1) command, such as \fBLWP\fR status, \fBCPU\fR usage,
388 \fBnice\fR value, \fBLWP-ID\fR, and so forth. The \fBlwpsinfo_t\fR structure is
389 defined in <\fBsys/procfs.h\fR>. This is the only entry present for a zombie
390 LWP.
391 .RE

393 .sp
394 .ne 2
395 .na
396 \fB\fBlwpstatus_t\fR\fR
397 .ad
398 .RS 15n
399 \fBn_type\fR: \fBNT_LWPSTATUS\fR. This structure contains things of interest to
400 a debugger from the operating system, such as the general registers, the
401 floating point registers, state, reason for stopping, \fBLWP-ID\fR, and so
402 forth. The \fBlwpstatus_t\fR structure is defined in <\fBsys/procfs.h>\fR>.
403 .RE

405 .sp
406 .ne 2
407 .na
408 \fB\fBgwindows_t\fR\fR
409 .ad
410 .RS 15n
411 \fBn_type\fR: \fBNT_GWINDOWS\fR. This entry is present only on a SPARC machine
412 and only if the system was unable to flush all of the register windows to the
413 stack. It contains all of the unspilled register windows. The \fBgwindows_t\fR
414 structure is defined in \fB<sys/regset.h>\fR\&.
415 .RE

417 .sp
418 .ne 2
419 .na
420 \fB\fBprxregset_t\fR\fR
421 .ad
422 .RS 15n
423 \fBn_type\fR: \fBNT_PRXREG\fR. This entry is present only if the machine has
424 extra register state associated with it. It contains the extra register state.
425 The \fBprxregset_t\fR structure is defined in \fB<sys/procfs_isa.h>\fR\&.
426 .RE

428 .sp
429 .ne 2
430 .na
431 \fB\fBasrset_t\fR\fR
432 .ad
433 .RS 15n
434 \fBn_type\fR: \fBNT_ASRS\fR. This entry is present only on a SPARC V9 machine
435 and only if the process is a 64-bit process. It contains the ancillary state
436 registers for the \fBLWP.\fR The \fBasrset_t\fR structure is defined in

.TH PROC 4 "Jun 6, 2016"
.TH PROC 4 "Mar 31, 2013"
.SH NAME
proc \- /proc, the process file system
.SH DESCRIPTION
.sp
.LP
\fB/proc\fR is a file system that provides access to the state of each process
and light-weight process (lwp) in the system. The name of each entry in the
\fB/proc\fR directory is a decimal number corresponding to a process-ID. These
entries are themselves subdirectories. Access to process state is provided by
additional files contained within each subdirectory; the hierarchy is described
more completely below. In this document, ''\fB/proc\fR file'' refers to a
non-directory file within the hierarchy rooted at \fB/proc\fR. The owner of
each \fB/proc\fR file and subdirectory is determined by the user-ID of the
process.
.sp
.LP
\fB/proc\fR can be mounted on any mount point, in addition to the standard
\fB/proc\fR mount point, and can be mounted several places at once. Such
additional mounts are allowed in order to facilitate the confinement of
processes to subtrees of the file system via \fBchroot\fR(1M) and yet allow
such processes access to commands like \fBps\fR(1).
.sp
.LP
Standard system calls are used to access \fB/proc\fR files: \fBopen\fR(2),
\fBclose\fR(2), \fBread\fR(2), and \fBwrite\fR(2) (including \fBreadv\fR(2),
\fBwritev\fR(2), \fBpread\fR(2), and \fBpwrite\fR(2)). Most files describe
process state and can only be opened for reading. \fBctl\fR and \fBlwpctl\fR
(control) files permit manipulation of process state and can only be opened for
writing. \fBas\fR (address space) files contain the image of the running
process and can be opened for both reading and writing. An open for writing
allows process control; a read-only open allows inspection but not control. In
this document, we refer to the process as open for reading or writing if any of
its associated \fB/proc\fR files is open for reading or writing.
.sp
.LP
In general, more than one process can open the same \fB/proc\fR file at the
same time. \fIExclusive\fR \fIopen\fR is an advisory mechanism provided to
allow controlling processes to avoid collisions with each other. A process can
obtain exclusive control of a target process, with respect to other cooperating
processes, if it successfully opens any \fB/proc\fR file in the target process
for writing (the \fBas\fR or \fBctl\fR files, or the \fBlwpctl\fR file of any
lwp) while specifying \fBO_EXCL\fR in the \fBopen\fR(2). Such an open will fail
if the target process is already open for writing (that is, if an \fBas\fR,
\fBctl\fR, or \fBlwpctl\fR file is already open for writing). There can be any
number of concurrent read-only opens; \fBO_EXCL\fR is ignored on opens for
reading. It is recommended that the first open for writing by a controlling
process use the \fBO_EXCL\fR flag; multiple controlling processes usually
result in chaos.
```

```
.sp
.LP
If a process opens one of its own \fB/proc\fR files for writing, the open
succeeds regardless of \fBO_EXCL\fR and regardless of whether some other
process has the process open for writing. Self-opens do not count when another
process attempts an exclusive open. (A process cannot exclude a debugger by
opening itself for writing and the application of a debugger cannot prevent a
process from opening itself.) All self-opens for writing are forced to be
close-on-exec (see the \fBF_SETFD\fR operation of \fBfcntl\fR(2)).
.sp
.LP
Data may be transferred from or to any locations in the address space of the
traced process by applying \fBlseek\fR(2) to position the \fBas\fR file at the
virtual address of interest followed by \fBread\fR(2) or \fBwrite\fR(2) (or by
using \fBpread\fR(2) or \fBpwrite\fR(2) for the combined operation). The
address-map files \fB/proc/\fR\fIpid\fR\fB/map\fR and
\fB/proc/\fR\fIpid\fR\fB/xmap\fR can be read to determine the accessible areas
(mappings) of the address space. \fBI/O\fR transfers may span contiguous
mappings. An \fBI/O\fR request extending into an unmapped area is truncated at
the boundary. A write request beginning at an unmapped virtual address fails
with \fBEIO\fR; a read request beginning at an unmapped virtual address returns
zero (an end-of-file indication).
.sp
.LP
Information and control operations are provided through additional files.
\fB<procfs.h>\fR contains definitions of data structures and message formats
used with these files. Some of these definitions involve the use of sets of
flags. The set types \fBsigset_t\fR, \fBfltset_t\fR, and \fBsysset_t\fR
correspond, respectively, to signal, fault, and system call enumerations
defined in \fB<sys/signal.h>\fR, \fB<sys/fault.h>\fR, and
\fB<sys/syscall.h>\fR\&. Each set type is large enough to hold flags for its
own enumeration. Although they are of different sizes, they have a common
structure and can be manipulated by these macros:
.sp
.in +2
.nf
prfillset(&set);             /* turn on all flags in set */
premptyset(&set);            /* turn off all flags in set */
praddset(&set, flag);        /* turn on the specified flag */
prdelset(&set, flag);        /* turn off the specified flag */
r = prismember(&set, flag);  /* != 0 iff flag is turned on */
.fi
.in -2

.sp
.LP
One of \fBprfillset()\fR or \fBpremptyset()\fR must be used to initialize
\fBset\fR before it is used in any other operation. \fBflag\fR must be a member
of the enumeration corresponding to \fBset\fR.
.sp
.LP
Every process contains at least one \fIlight-weight process\fR, or \fIlwp\fR.
Each lwp represents a flow of execution that is independently scheduled by the
operating system. All lwps in a process share its address space as well as many
other attributes. Through the use of \fBlwpctl\fR and \fBctl\fR files as
described below, it is possible to affect individual lwps in a process or to
affect all of them at once, depending on the operation.
.sp
.LP
When the process has more than one lwp, a representative lwp is chosen by the
system for certain process status files and control operations. The
representative lwp is a stopped lwp only if all of the process's lwps are
stopped; is stopped on an event of interest only if all of the lwps are so
stopped (excluding \fBPR_SUSPENDED\fR lwps); is in a \fBPR_REQUESTED\fR stop
only if there are no other events of interest to be found; or, failing
everything else, is in a \fBPR_SUSPENDED\fR stop (implying that the process is
```

deadlocked). See the description of the \fBstatus\fR file for definitions of stopped states. See the \fBPCSTOP\fR control operation for the definition of ‘‘event of interest’’.

.sp

.LP

The representative lwp remains fixed (it will be chosen again on the next operation) as long as all of the lwps are stopped on events of interest or are in a \fBPR_SUSPENDED\fR stop and the \fBPCRUN\fR control operation is not applied to any of them.

.sp

.LP

When applied to the process control file, every \fB/proc\fR control operation that must act on an lwp uses the same algorithm to choose which lwp to act upon. Together with synchronous stopping (see \fBPCSET\fR), this enables a debugger to control a multiple-lwp process using only the process-level status and control files if it so chooses. More fine-grained control can be achieved using the lwp-specific files.

.sp

.LP

The system supports two process data models, the traditional 32-bit data model in which ints, longs and pointers are all 32 bits wide (the ILP32 data model), and on some platforms the 64-bit data model in which longs and pointers, but not ints, are 64 bits in width (the LP64 data model). In the LP64 data model some system data types, notably \fBsize_t\fR, \fBoff_t\fR, \fBtime_t\fR and \fBdev_t\fR, grow from 32 bits to 64 bits as well.

.sp

.LP

The \fB/proc\fR interfaces described here are available to both 32-bit and 64-bit controlling processes. However, many operations attempted by a 32-bit controlling process on a 64-bit target process will fail with \fBEOVERFLOW\fR because the address space range of a 32-bit process cannot encompass a 64-bit process or because the data in some 64-bit system data type cannot be compressed to fit into the corresponding 32-bit type without loss of information. Operations that fail in this circumstance include reading and writing the address space, reading the address-map files, and setting the target process’s registers. There is no restriction on operations applied by a 64-bit process to either a 32-bit or a 64-bit target processes.

.sp

.LP

The format of the contents of any \fB/proc\fR file depends on the data model of the observer (the controlling process), not on the data model of the target process. A 64-bit debugger does not have to translate the information it reads from a \fB/proc\fR file for a 32-bit process from 32-bit format to 64-bit format. However, it usually has to be aware of the data model of the target process. The \fBpr_dmodel\fR field of the \fBstatus\fR files indicates the target process’s data model.

.sp

.LP

To help deal with system data structures that are read from 32-bit processes, a 64-bit controlling program can be compiled with the C preprocessor symbol \fB_SYSCALL32\fR defined before system header files are included. This makes explicit 32-bit fixed-width data structures (like \fBcstruct stat32\fR) visible to the 64-bit program. See \fBtypes32.h\fR(3HEAD).

.SH DIRECTORY STRUCTURE

.sp

.LP

At the top level, the directory \fB/proc\fR contains entries each of which names an existing process in the system. These entries are themselves directories. Except where otherwise noted, the files described below can be opened for reading only. In addition, if a process becomes a \fIzombie\fR (one that has exited but whose parent has not yet performed a \fBwait\fR(3C) upon it), most of its associated \fB/proc\fR files disappear from the hierarchy; subsequent attempts to open them, or to read or write files opened before the process exited, will elicit the error \fBENOENT\fR.

.sp

.LP

Although process state and consequently the contents of \fB/proc\fR files can change from instant to instant, a single \fBread\fR(2) of a \fB/proc\fR file is guaranteed to return a sane representation of state; that is, the read will be atomic with respect to the state of the process. No such guarantee applies to successive reads applied to a \fB/proc\fR file for a running process. In addition, atomicity is not guaranteed for \fBI/O\fR applied to the \fBas\fR (address-space) file for a running process or for a process whose address space contains memory shared by another running process.

.sp

.LP

A number of structure definitions are used to describe the files. These structures may grow by the addition of elements at the end in future releases of the system and it is not legitimate for a program to assume that they will not.

.SH STRUCTURE OF \fB/proc/\fR\fIpid\fR

.sp

.LP

A given directory \fB/proc/\fR\fIpid\fR contains the following entries. A process can use the invisible alias \fB/proc/self\fR if it wishes to open one of its own \fB/proc\fR files (invisible in the sense that the name ‘‘self’’ does not appear in a directory listing of \fB/proc\fR obtained from \fBls\fR(1), \fBgetdents\fR(2), or \fBreaddir\fR(3C)).

.SS "contracts"

.sp

.LP

A directory containing references to the contracts held by the process. Each entry is a symlink to the contract’s directory under \fB/system/contract\fR. See \fBcontract\fR(4).

.SS "as"

.sp

.LP

Contains the address-space image of the process; it can be opened for both reading and writing. \fBlseek\fR(2) is used to position the file at the virtual address of interest and then the address space can be examined or changed through \fBread\fR(2) or \fBwrite\fR(2) (or by using \fBpread\fR(2) or \fBpwrite\fR(2) for the combined operation).

.SS "ctl"

.sp

.LP

A write-only file to which structured messages are written directing the system to change some aspect of the process’s state or control its behavior in some way. The seek offset is not relevant when writing to this file. Individual lwps also have associated \fBlwpctl\fR files in the lwp subdirectories. A control message may be written either to the process’s \fBctl\fR file or to a specific \fBlwpctl\fR file with operation-specific effects. The effect of a control message is immediately reflected in the state of the process visible through appropriate status and information files. The types of control messages are described in detail later. See \fBCONTROL MESSAGES\fR.

.SS "status"

.sp

.LP

Contains state information about the process and the representative lwp. The file contains a \fBpstatus\fR structure which contains an embedded \fBlwpstatus\fR structure for the representative lwp, as follows:

.sp

.in +2

.nf

```
typedef struct pstatus {
     int pr_flags;          /* flags (see below) */
     int pr_nlwp;           /* number of active lwps in the process */
     int pr_nzomb;          /* number of zombie lwps in the process */
     pid_tpr_pid;           /* process id */
     pid_tpr_ppid;          /* parent process id */
     pid_tpr_pgid;          /* process group id */
     pid_tpr_sid;           /* session id */
     id_t pr_aslwpid;       /* obsolete */
```

```
248      id_t pr_agentid;         /* lwp-id of the agent lwp, if any */

593 \fBpr_lwpid\fR names the specific lwp.
594 .sp
595 .LP
596 \fBpr_why\fR and \fBpr_what\fR together describe, for a stopped lwp, the reason
597 for the stop. Possible values of \fBpr_why\fR and the associated \fBpr_what\fR
598 are:
599 .sp
600 .ne 2
601 .na
602 \fB\fBPR_REQUESTED\fR\fR
603 .ad
```

```
.RS 17n
indicates that the stop occurred in response to a stop directive, normally
because \fBPCSTOP\fR was applied or because another lwp stopped on an event of
interest and the asynchronous-stop flag (see \fBPCSET\fR) was not set for the
process. \fBpr_what\fR is unused in this case.
.RE

.sp
.ne 2
.na
\fB\fBPR_SIGNALLED\fR\fR
.ad
.RS 17n
indicates that the lwp stopped on receipt of a signal (see \fBPCSTRACE\fR);
\fBpr_what\fR holds the signal number that caused the stop (for a newly-stopped
lwp, the same value is in \fBpr_cursig\fR).
.RE

.sp
.ne 2
.na
\fB\fBPR_FAULTED\fR\fR
.ad
.RS 17n
indicates that the lwp stopped on incurring a hardware fault (see
\fBPCSFAULT\fR); \fBpr_what\fR holds the fault number that caused the stop.
.RE

.sp
.ne 2
.na
\fB\fBPR_SYSENTRY\fR\fR
.ad
.br
.na
\fB\fBPR_SYSEXIT\fR\fR
.ad
.RS 17n
indicate a stop on entry to or exit from a system call (see \fBPCSENTRY\fR and
\fBPCSEXIT\fR); \fBpr_what\fR holds the system call number.
.RE

.sp
.ne 2
.na
\fB\fBPR_JOBCONTROL\fR\fR
.ad
.RS 17n
indicates that the lwp stopped due to the default action of a job control stop
signal (see \fBsigaction\fR(2)); \fBpr_what\fR holds the stopping signal
number.
.RE

.sp
.ne 2
.na
\fB\fBPR_SUSPENDED\fR\fR
.ad
.RS 17n
indicates that the lwp stopped due to internal synchronization of lwps within
the process. \fBpr_what\fR is unused in this case.
.RE

.sp
.LP
\fBpr_cursig\fR names the current signal, that is, the next signal to be
```

```
delivered to the lwp, if any. \fBpr_info\fR, when the lwp is in a
\fBPR_SIGNALLED\fR or \fBPR_FAULTED\fR stop, contains additional information
pertinent to the particular signal or fault (see \fB<sys/siginfo.h>\fR).
.sp
.LP
\fBpr_lwppend\fR identifies any synchronous or directed signals pending for the
lwp. \fBpr_lwphold\fR identifies those signals whose delivery is being blocked
by the lwp (the signal mask).
.sp
.LP
\fBpr_action\fR contains the signal action information pertaining to the
current signal (see \fBsigaction\fR(2)); it is undefined if \fBpr_cursig\fR is
zero. \fBpr_altstack\fR contains the alternate signal stack information for the
lwp (see \fBsigaltstack\fR(2)).
.sp
.LP
\fBpr_oldcontext\fR, if not zero, contains the address on the lwp stack of a
\fBucontext\fR structure describing the previous user-level context (see
\fBucontext.h\fR(3HEAD)). It is non-zero only if the lwp is executing in the
context of a signal handler.
.sp
.LP
\fBpr_syscall\fR is the number of the system call, if any, being executed by
the lwp; it is non-zero if and only if the lwp is stopped on \fBPR_SYSENTRY\fR
or \fBPR_SYSEXIT\fR, or is asleep within a system call ( \fBPR_ASLEEP\fR is
set). If \fBpr_syscall\fR is non-zero, \fBpr_nsysarg\fR is the number of
arguments to the system call and \fBpr_sysarg\fR contains the actual arguments.
.sp
.LP
\fBpr_rval1\fR, \fBpr_rval2\fR, and \fBpr_errno\fR are defined only if the lwp
is stopped on \fBPR_SYSEXIT\fR or if the \fBPR_VFORKP\fR flag is set. If
\fBpr_errno\fR is zero, \fBpr_rval1\fR and \fBpr_rval2\fR contain the return
values from the system call. Otherwise, \fBpr_errno\fR contains the error
number for the failing system call (see \fB<sys/errno.h>\fR).
.sp
.LP
\fBpr_clname\fR contains the name of the lwp's scheduling class.
.sp
.LP
\fBpr_tstamp\fR, if the lwp is stopped, contains a time stamp marking when the
lwp stopped, in real time seconds and nanoseconds since an arbitrary time in
the past.
.sp
.LP
\fBpr_utime\fR is the amount of user level CPU time used by this LWP.
.sp
.LP
\fBpr_stime\fR is the amount of system level CPU time used by this LWP.
.sp
.LP
\fBpr_ustack\fR is the virtual address of the \fBstack_t\fR that contains the
stack boundaries for this LWP. See \fBgetustack\fR(2) and
\fB_stack_grow\fR(3C).
.sp
.LP
\fBpr_instr\fR contains the machine instruction to which the lwp's program
counter refers. The amount of data retrieved from the process is
machine-dependent. On SPARC based machines, it is a 32-bit word. On x86-based
machines, it is a single byte. In general, the size is that of the machine's
smallest instruction. If \fBPR_PCINVAL\fR is set, \fBpr_instr\fR is undefined;
this occurs whenever the lwp is not stopped or when the program counter refers
to an invalid virtual address.
.sp
.LP
\fBpr_reg\fR is an array holding the contents of a stopped lwp's general
registers.
```

```
 736 .sp
 737 .ne 2
 738 .na
 739 \fBSPARC\fR
 740 .ad
 741 .RS 21n
 742 On SPARC-based machines, the predefined constants \fBR_G0\fR ... \fBR_G7\fR,
 743 \fBR_O0\fR ... \fBR_O7\fR, \fBR_L0\fR ... \fBR_L7\fR, \fBR_I0\fR ...
 744 \fBR_I7\fR, \fBR_PC\fR, \fBR_nPC\fR, and \fBR_Y\fR can be used as indices to
 745 refer to the corresponding registers; previous register windows can be read
 746 from their overflow locations on the stack (however, see the \fBgwindows\fR
 747 file in the \fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid\fR subdirectory).

1049 } prsecflags_t;
1050 .in -2

1052 .sp
1053 .LP
1054 The \fBpr_version\fR field is a version number for the structure, currently
1055 \fBPRSECFLAGS_VERSION_1\fR.
1056 #endif /* ! codereview */
1057 .SS "sigact"
1046 .sp
1058 .LP
1059 Contains an array of \fBsigaction structures\fR describing the current
1060 dispositions of all signals associated with the traced process (see
1061 \fBsigaction\fR(2)). Signal numbers are displaced by 1 from array indices, so
1062 that the action for signal number \fIn\fR appears in position \fIn\fR-1 of the
1063 array.
1064 .SS "auxv"
1054 .sp
1065 .LP
1066 Contains the initial values of the process's aux vector in an array of
1067 \fBauxv_t\fR structures (see \fB<sys/auxv.h>\fR). The values are those that
1068 were passed by the operating system as startup information to the dynamic
1069 linker.
1070 .SS "ldt"
1061 .sp
1071 .LP
1072 This file exists only on x86-based machines. It is non-empty only if the
1073 process has established a local descriptor table (\fBLDT\fR). If non-empty, the
1074 file contains the array of currently active \fBLDT\fR entries in an array of
1075 elements of type \fBstruct ssd\fR, defined in \fB<sys/sysi86.h>\fR, one element
1076 for each active \fBLDT\fR entry.
1077 .SS "map, xmap"
1069 .sp
1078 .LP
1079 Contain information about the virtual address map of the process. The map file
1080 contains an array of \fBprmap\fR structures while the xmap file contains an
1081 array of \fBprxmap\fR structures. Each structure describes a contiguous virtual
1082 address region in the address space of the traced process:
1083 .sp
1084 .in +2
1085 .nf
1086 typedef struct prmap {
1087         uintptr_tpr_vaddr;         /* virtual address of mapping */
1088         size_t pr_size;            /* size of mapping in bytes */
1089         char pr_mapname[PRMAPSZ];  /* name in /proc/pid/object */
1090         offset_t pr_offset;        /* offset into mapped object, if any */
1091         int pr_mflags;             /* protection and attribute flags */
1092         int pr_pagesize;           /* pagesize for this mapping in bytes */
1093         int pr_shmid;              /* SysV shared memory identifier */
1094 } prmap_t;

1193 .ad
1194 .RS 17n
1195 mapping System V shared memory
```

```
.RE

.sp
.LP
A contiguous area of the address space having the same underlying mapped object
may appear as multiple mappings due to varying read, write, and execute
attributes. The underlying mapped object does not change over the range of a
single mapping. An \fBI/O\fR operation to a mapping marked \fBMA_SHARED\fR
fails if applied at a virtual address not corresponding to a valid page in the
underlying mapped object. A write to a \fBMA_SHARED\fR mapping that is not
marked \fBMA_WRITE\fR fails. Reads and writes to private mappings always
succeed. Reads and writes to unmapped addresses fail.
.sp
.LP
\fBpr_pagesize\fR is the page size for the mapping, currently always the system
pagesize.
.sp
.LP
\fBpr_shmid\fR is the shared memory identifier, if any, for the mapping. Its
value is \fB\(mi1\fR if the mapping is not System V shared memory. See
\fBshmget\fR(2).
.sp
.LP
\fBpr_dev\fR is the device of the mapped object, if any, for the mapping. Its
value is \fBPRNODEV\fR (-1) if the mapping does not have a device.
.sp
.LP
\fBpr_ino\fR is the inode of the mapped object, if any, for the mapping. Its
contents are only valid if \fBpr_dev\fR is not \fBPRNODEV.\fR
.sp
.LP
\fBpr_rss\fR is the number of resident pages of memory for the mapping. The
number of resident bytes for the mapping may be determined by multiplying
\fBpr_rss\fR by the page size given by \fBpr_pagesize.\fR
.sp
.LP
\fBpr_anon\fR is the number of resident anonymous memory pages (pages which are
private to this process) for the mapping.
.sp
.LP
\fBpr_locked\fR is the number of locked pages for the mapping. Pages which are
locked are always resident in memory.
.sp
.LP
\fBpr_hatpagesize\fR is the size, in bytes, of the \fBHAT\fR (\fBMMU\fR)
translation for the mapping. \fBpr_hatpagesize\fR may be different than
\fBpr_pagesize.\fR The possible values are hardware architecture specific, and
may change over a mapping's lifetime.
.SS "rmap"
.sp
.LP
Contains information about the reserved address ranges of the process. The file
contains an array of \fBprmap\fR structures, as defined above for the \fBmap\fR
file. Each structure describes a contiguous virtual address region in the
address space of the traced process that is reserved by the system in the sense
that an \fBmmap\fR(2) system call that does not specify \fBMAP_FIXED\fR will
not use any part of it for the new mapping. Examples of such reservations
include the address ranges reserved for the process stack and the individual
thread stacks of a multi-threaded process.
.SS "cwd"
.sp
.LP
A symbolic link to the process's current working directory. See \fBchdir\fR(2).
A \fBreadlink\fR(2) of \fB/proc/\fIpid\fR/cwd\fR yields a null string. However,
it can be opened, listed, and searched as a directory, and can be the target of
\fBchdir\fR(2).
```

```
.SS "root"
.sp
.LP
A symbolic link to the process's root directory.
\fB/proc/\fR\fIpid\fR\fB/root\fR can differ from the system root directory if
the process or one of its ancestors executed \fBchroot\fR(2) as super user. It
has the same semantics as \fB/proc/\fR\fIpid\fR\fB/cwd\fR.
.SS "fd"
.sp
.LP
A directory containing references to the open files of the process. Each entry
is a decimal number corresponding to an open file descriptor in the process.
.sp
.LP
If an entry refers to a regular file, it can be opened with normal file system
semantics but, to ensure that the controlling process cannot gain greater
access than the controlled process, with no file access modes other than its
read/write open modes in the controlled process. If an entry refers to a
directory, it can be accessed with the same semantics as
\fB/proc/\fIpid\fR/cwd\fR. An attempt to open any other type of entry fails
with \fBEACCES\fR.
.SS "object"
.sp
.LP
A directory containing read-only files with names corresponding to the
\fBpr_mapname\fR entries in the \fBmap\fR and \fBpagedata\fR files. Opening
such a file yields a file descriptor for the underlying mapped file associated
with an address-space mapping in the process. The file name \fBa.out\fR appears
in the directory as an alias for the process's executable file.
.sp
.LP
The \fBobject\fR directory makes it possible for a controlling process to gain
access to the object file and any shared libraries (and consequently the symbol
tables) without having to know the actual path names of the executable files.
.SS "path"
.sp
.LP
A directory containing symbolic links to files opened by the process. The
directory includes one entry for \fBcwd\fR and \fBroot\fR. The directory also
contains a numerical entry for each file descriptor in the \fBfd\fR directory,
and entries matching those in the \fBobject\fR directory. If this information
is not available, any attempt to read the contents of the symbolic link will
fail. This is most common for files that do not exist in the filesystem
namespace (such as \fBFIFO\fRs and sockets), but can also happen for regular
files. For the file descriptor entries, the path may be different from the one
used by the process to open the file.
.SS "pagedata"
.sp
.LP
Opening the page data file enables tracking of address space references and
modifications on a per-page basis.
.sp
.LP
A \fBread\fR(2) of the page data file descriptor returns structured page data
and atomically clears the page data maintained for the file by the system. That
is to say, each read returns data collected since the last read; the first read
returns data collected since the file was opened. When the call completes, the
read buffer contains the following structure as its header and thereafter
contains a number of section header structures and associated byte arrays that
must be accessed by walking linearly through the buffer.
.sp
.in +2
.nf
typedef struct prpageheader {
    timestruc_t pr_tstamp; /* real time stamp, time of read() */
    ulong_t pr_nmap;       /* number of address space mappings */
```

```
    ulong_t pr_npage;      /* total number of pages */
} prpageheader_t;
_____unchanged_portion_omitted_
.fi
.in -2

.sp
.LP
Each section header is followed by \fBpr_npage\fR bytes, one byte for each page
in the mapping, plus 0-7 null bytes at the end so that the next \fBprasmap\fR
structure begins on an eight-byte aligned boundary. Each data byte may contain
these flags:
.sp
.ne 2
.na
\fB\fBPG_REFERENCED\fR\fR
.ad
.RS 17n
page has been referenced.
.RE

.sp
.ne 2
.na
\fB\fBPG_MODIFIED\fR\fR
.ad
.RS 17n
page has been modified.
.RE

.sp
.LP
If the read buffer is not large enough to contain all of the page data, the
read fails with \fBE2BIG\fR and the page data is not cleared. The required size
of the read buffer can be determined through \fBfstat\fR(2). Application of
\fBlseek\fR(2) to the page data file descriptor is ineffective; every read
starts from the beginning of the file. Closing the page data file descriptor
terminates the system overhead associated with collecting the data.
.sp
.LP
More than one page data file descriptor for the same process can be opened, up
to a system-imposed limit per traced process. A read of one does not affect the
data being collected by the system for the others. An open of the page data
file will fail with \fBENOMEM\fR if the system-imposed limit would be exceeded.
.SS "watch"
.sp
.LP
Contains an array of \fBprwatch\fR structures, one for each watched area
established by the \fBPCWATCH\fR control operation. See \fBPCWATCH\fR for
details.
.SS "usage"
.sp
.LP
Contains process usage information described by a \fBprusage\fR structure which
contains at least the following fields:
.sp
.in +2
.nf
typedef struct prusage {
    id_t pr_lwpid;          /* lwp id.  0: process or defunct */
    int pr_count;           /* number of contributing lwps */
    timestruc_t pr_tstamp;  /* real time stamp, time of read() */
    timestruc_t pr_create;  /* process/lwp creation time stamp */
    timestruc_t pr_term;    /* process/lwp termination time stamp */
    timestruc_t pr_rtime;   /* total lwp real (elapsed) time */
    timestruc_t pr_utime;   /* user level CPU time */
```

```
    timestruc_t pr_stime;   /* system call CPU time */
    timestruc_t pr_ttime;   /* other system trap CPU time */
    timestruc_t pr_tftime;  /* text page fault sleep time */
    timestruc_t pr_dftime;  /* data page fault sleep time */
    timestruc_t pr_kftime;  /* kernel page fault sleep time */
    timestruc_t pr_ltime;   /* user lock wait sleep time */
    timestruc_t pr_slptime; /* all other sleep time */
    timestruc_t pr_wtime;   /* wait-cpu (latency) time */
    timestruc_t pr_stoptime; /* stopped time */
    ulong_t pr_minf;        /* minor page faults */
    ulong_t pr_majf;        /* major page faults */
    ulong_t pr_nswap;       /* swaps */
    ulong_t pr_inblk;       /* input blocks */
    ulong_t pr_oublk;       /* output blocks */
    ulong_t pr_msnd;        /* messages sent */
    ulong_t pr_mrcv;        /* messages received */
    ulong_t pr_sigs;        /* signals received */
    ulong_t pr_vctx;        /* voluntary context switches */
    ulong_t pr_ictx;        /* involuntary context switches */
    ulong_t pr_sysc;        /* system calls */
    ulong_t pr_ioch;        /* chars read and written */
} prusage_t;
.fi
.in -2

.sp
.LP
Microstate accounting is now continuously enabled. While this information was
previously an estimate, if microstate accounting were not enabled, the current
information is now never an estimate represents time the process has spent in
various states.
.SS "lstatus"
.sp
.LP
Contains a \fBprheader\fR structure followed by an array of \fBlwpstatus\fR
structures, one for each active lwp in the process (see also
\fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid\fR/\fBlwpstatus\fR, below). The
\fBprheader\fR structure describes the number and size of the array entries
that follow.
.sp
.in +2
.nf
typedef struct prheader {
    long pr_nent;       /* number of entries */
    size_t pr_entsize;  /* size of each entry, in bytes */
} prheader_t;
.fi
.in -2

.sp
.LP
The \fBlwpstatus\fR structure may grow by the addition of elements at the end
in future releases of the system. Programs must use \fBpr_entsize\fR in the
file header to index through the array. These comments apply to all \fB/proc\fR
files that include a \fBprheader\fR structure (\fBlpsinfo\fR and \fBlusage\fR,
below).
.SS "lpsinfo"
.sp
.LP
Contains a \fBprheader\fR structure followed by an array of \fBlwpsinfo\fR
structures, one for eachactive and zombie lwp in the process. See also
\fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid\fR/\fBlwpsinfo\fR, below.
.SS "lusage"
.sp
.LP
Contains a \fBprheader\fR structure followed by an array of \fBprusage\fR
```

structures, one for each active lwp in the process, plus an additional element at the beginning that contains the summation over all defunct lwps (lwps that once existed but no longer exist in the process). Excluding the \fBpr_lwpid\fR, \fBpr_tstamp\fR, \fBpr_create\fR, and \fBpr_term\fR entries, the entry-by-entry summation over all these structures is the definition of the process usage information obtained from the \fBusage\fR file. (See also \fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid\fR/\fBlwpusage\fR, below.)
.SS "lwp"
.sp
.LP
A directory containing entries each of which names an active or zombie lwp within the process. These entries are themselves directories containing additional files as described below. Only the \fBlwpsinfo\fR file exists in the directory of a zombie lwp.
.SH STRUCTURE OF \fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid\fR
.sp
.LP
A given directory \fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid\fR contains the following entries:
.SS "lwpctl"
.sp
.LP
Write-only control file. The messages written to this file affect the specific lwp rather than the representative lwp, as is the case for the process's \fBctl\fR file.
.SS "lwpstatus"
.sp
.LP
lwp-specific state information. This file contains the \fBlwpstatus\fR structure for the specific lwp as described above for the representative lwp in the process's \fBstatus\fR file.
.SS "lwpsinfo"
.sp
.LP
lwp-specific \fBps\fR(1) information. This file contains the \fBlwpsinfo\fR structure for the specific lwp as described above for the representative lwp in the process's \fBpsinfo\fR file. The \fBlwpsinfo\fR file remains accessible after an lwp becomes a zombie.
.SS "lwpusage"
.sp
.LP
This file contains the \fBprusage\fR structure for the specific lwp as described above for the process's \fBusage\fR file.
.SS "gwindows"
.sp
.LP
This file exists only on SPARC based machines. If it is non-empty, it contains a \fBgwindows_t\fR structure, defined in \fB<sys/regset.h>\fR, with the values of those SPARC register windows that could not be stored on the stack when the lwp stopped. Conditions under which register windows are not stored on the stack are: the stack pointer refers to nonexistent process memory or the stack pointer is improperly aligned. If the lwp is not stopped or if there are no register windows that could not be stored on the stack, the file is empty (the usual case).
.SS "xregs"
.sp
.LP
Extra state registers. The extra state register set is architecture dependent; this file is empty if the system does not support extra state registers. If the file is non-empty, it contains an architecture dependent structure of type \fBprxregset_t\fR, defined in \fB<procfs.h>\fR, with the values of the lwp's extra state registers. If the lwp is not stopped, all register values are undefined. See also the \fBPCSXREG\fR control operation, below.
.SS "asrs"
.sp
.LP

This file exists only for 64-bit SPARC V9 processes. It contains an \fBasrset_t\fR structure, defined in <\fBsys/regset.h\fR>, containing the values of the lwp's platform-dependent ancillary state registers. If the lwp is not stopped, all register values are undefined. See also the \fBPCSASRS\fR control operation, below.
.SS "spymaster"
.sp
.LP
For an agent lwp (see \fBPCAGENT\fR), this file contains a \fBpsinfo_t\fR structure that corresponds to the process that created the agent lwp at the time the agent was created. This structure is identical to that retrieved via the \fBpsinfo\fR file, with one modification: the \fBpr_time\fR field does not correspond to the CPU time for the process, but rather to the creation time of the agent lwp.
.SS "templates"
.sp
.LP
A directory which contains references to the active templates for the lwp, named by the contract type. Changes made to an active template descriptor do not affect the original template which was activated, though they do affect the active template. It is not possible to activate an active template descriptor. See \fBcontract\fR(4).
.SH CONTROL MESSAGES
.sp
.LP
Process state changes are effected through messages written to a process's \fBctl\fR file or to an individual lwp's \fBlwpctl\fR file. All control messages consist of a \fBlong\fR that names the specific operation followed by additional data containing the operand, if any.
.sp
.LP
Multiple control messages may be combined in a single \fBwrite\fR(2) (or \fBwritev\fR(2)) to a control file, but no partial writes are permitted. That is, each control message, operation code plus operand, if any, must be presented in its entirety to the \fBwrite\fR(2) and not in pieces over several system calls. If a control operation fails, no subsequent operations contained in the same \fBwrite\fR(2) are attempted.
.sp
.LP
Descriptions of the allowable control messages follow. In all cases, writing a message to a control file for a process or lwp that has terminated elicits the error \fBENOENT\fR.
.SS "PCSTOP PCDSTOP PCWSTOP PCTWSTOP"
.sp
.LP
When applied to the process control file, \fBPCSTOP\fR directs all lwps to stop and waits for them to stop, \fBPCDSTOP\fR directs all lwps to stop without waiting for them to stop, and \fBPCWSTOP\fR simply waits for all lwps to stop. When applied to an lwp control file, \fBPCSTOP\fR directs the specific lwp to stop and waits until it has stopped, \fBPCDSTOP\fR directs the specific lwp to stop without waiting for it to stop, and \fBPCWSTOP\fR simply waits for the specific lwp to stop. When applied to an lwp control file, \fBPCSTOP\fR and \fBPCWSTOP\fR complete when the lwp stops on an event of interest, immediately if already so stopped; when applied to the process control file, they complete when every lwp has stopped either on an event of interest or on a \fBPR_SUSPENDED\fR stop.
.sp
.LP
\fBPCTWSTOP\fR is identical to \fBPCWSTOP\fR except that it enables the operation to time out, to avoid waiting forever for a process or lwp that may never stop on an event of interest. \fBPCTWSTOP\fR takes a \fBlong\fR operand specifying a number of milliseconds; the wait will terminate successfully after the specified number of milliseconds even if the process or lwp has not stopped; a timeout value of zero makes the operation identical to \fBPCWSTOP\fR.
.sp

```
.LP
An ‘‘event of interest’’ is either a \fBPR_REQUESTED\fR stop or a stop that has
been specified in the process’s tracing flags (set by \fBPCSTRACE\fR,
\fBPCSFAULT\fR, \fBPCSENTRY\fR, and \fBPCSEXIT\fR). \fBPR_JOBCONTROL\fR and
\fBPR_SUSPENDED\fR stops are specifically not events of interest. (An lwp may
stop twice due to a stop signal, first showing \fBPR_SIGNALLED\fR if the signal
is traced and again showing \fBPR_JOBCONTROL\fR if the lwp is set running
without clearing the signal.) If \fBPCSTOP\fR or \fBPCDSTOP\fR is applied to an
lwp that is stopped, but not on an event of interest, the stop directive takes
effect when the lwp is restarted by the competing mechanism. At that time, the
lwp enters a \fBPR_REQUESTED\fR stop before executing any user-level code.
.sp
.LP
A write of a control message that blocks is interruptible by a signal so that,
for example, an \fBalarm\fR(2) can be set to avoid waiting forever for a
process or lwp that may never stop on an event of interest. If \fBPCSTOP\fR is
interrupted, the lwp stop directives remain in effect even though the
\fBwrite\fR(2) returns an error. (Use of \fBPCTWSTOP\fR with a non-zero timeout
is recommended over \fBPCWSTOP\fR with an \fBalarm\fR(2).)
.sp
.LP
A system process (indicated by the \fBPR_ISSYS\fR flag) never executes at user
level, has no user-level address space visible through \fB/proc\fR, and cannot
be stopped. Applying one of these operations to a system process or any of its
lwps elicits the error \fBEBUSY\fR.
.SS "PCRUN"
.sp
.LP
Make an lwp runnable again after a stop. This operation takes a \fBlong\fR
operand containing zero or more of the following flags:
.sp
.ne 2
.na
\fB\fBPRCSIG\fR\fR
.ad
.RS 12n
clears the current signal, if any (see \fBPCCSIG\fR).
.RE

.sp
.ne 2
.na
\fB\fBPRCFAULT\fR\fR
.ad
.RS 12n
clears the current fault, if any (see \fBPCCFAULT\fR).
.RE

.sp
.ne 2
.na
\fB\fBPRSTEP\fR\fR
.ad
.RS 12n
directs the lwp to execute a single machine instruction. On completion of the
instruction, a trace trap occurs. If \fBFLTTRACE\fR is being traced, the lwp
stops; otherwise, it is sent \fBSIGTRAP\fR. If \fBSIGTRAP\fR is being traced
and is not blocked, the lwp stops. When the lwp stops on an event of interest,
the single-step directive is cancelled, even if the stop occurs before the
instruction is executed. This operation requires hardware and operating system
support and may not be implemented on all processors. It is implemented on
SPARC and x86-based machines.
.RE

.sp
.ne 2
```

```
.na
\fB\fBPRSABORT\fR\fR
.ad
.RS 12n
is meaningful only if the lwp is in a \fBPR_SYSENTRY\fR stop or is marked
\fBPR_ASLEEP\fR; it instructs the lwp to abort execution of the system call
(see \fBPCSENTRY\fR and \fBPCSEXIT\fR).
.RE

.sp
.ne 2
.na
\fB\fBPRSTOP\fR\fR
.ad
.RS 12n
directs the lwp to stop again as soon as possible after resuming execution (see
\fBPCDSTOP\fR). In particular, if the lwp is stopped on \fBPR_SIGNALLED\fR or
\fBPR_FAULTED\fR, the next stop will show \fBPR_REQUESTED\fR, no other stop
will have intervened, and the lwp will not have executed any user-level code.
.RE

.sp
.LP
When applied to an lwp control file, \fBPCRUN\fR clears any outstanding
directed-stop request and makes the specific lwp runnable. The operation fails
with \fBEBUSY\fR if the specific lwp is not stopped on an event of interest or
has not been directed to stop or if the agent lwp exists and this is not the
agent lwp (see \fBPCAGENT\fR).
.sp
.LP
When applied to the process control file, a representative lwp is chosen for
the operation as described for \fB/proc/\fR\fIpid\fR\fB/status\fR. The
operation fails with \fBEBUSY\fR if the representative lwp is not stopped on an
event of interest or has not been directed to stop or if the agent lwp exists.
If \fBPRSTEP\fR or \fBPRSTOP\fR was requested, the representative lwp is made
runnable and its outstanding directed-stop request is cleared; otherwise all
outstanding directed-stop requests are cleared and, if it was stopped on an
event of interest, the representative lwp is marked \fBPR_REQUESTED\fR. If, as
a consequence, all lwps are in the \fBPR_REQUESTED\fR or \fBPR_SUSPENDED\fR
stop state, all lwps showing \fBPR_REQUESTED\fR are made runnable.
.SS "PCSTRACE"
.sp
.LP
Define a set of signals to be traced in the process. The receipt of one of
these signals by an lwp causes the lwp to stop. The set of signals is defined
using an operand \fBsigset_t\fR contained in the control message. Receipt of
\fBSIGKILL\fR cannot be traced; if specified, it is silently ignored.
.sp
.LP
If a signal that is included in an lwp’s held signal set (the signal mask) is
sent to the lwp, the signal is not received and does not cause a stop until it
is removed from the held signal set, either by the lwp itself or by setting the
held signal set with \fBPCSHOLD\fR.
.SS "PCCSIG"
.sp
.LP
The current signal, if any, is cleared from the specific or representative lwp.
.SS "PCSSIG"
.sp
.LP
The current signal and its associated signal information for the specific or
representative lwp are set according to the contents of the operand
\fBsiginfo\fR structure (see \fB<sys/siginfo.h>\fR). If the specified signal
number is zero, the current signal is cleared. The semantics of this operation
are different from those of \fBkill\fR(2) in that the signal is delivered to
the lwp immediately after execution is resumed (even if it is being blocked)
```

```
1713 and an additional \fBPR_SIGNALLED\fR stop does not intervene even if the signal
1714 is traced. Setting the current signal to \fBSIGKILL\fR terminates the process
1715 immediately.
1716 .SS "PCKILL"
1738 .sp
1717 .LP
1718 If applied to the process control file, a signal is sent to the process with
1719 semantics identical to those of \fBkill\fR(2). If applied to an lwp control
1720 file, a directed signal is sent to the specific lwp. The signal is named in a
1721 \fBlong\fR operand contained in the message. Sending \fBSIGKILL\fR terminates
1722 the process immediately.
1723 .SS "PCUNKILL"
1746 .sp
1724 .LP
1725 A signal is deleted, that is, it is removed from the set of pending signals. If
1726 applied to the process control file, the signal is deleted from the process's
1727 pending signals. If applied to an lwp control file, the signal is deleted from
1728 the lwp's pending signals. The current signal (if any) is unaffected. The
1729 signal is named in a \fBlong\fR operand in the control message. It is an error
1730 (\fBEINVAL\fR) to attempt to delete \fBSIGKILL\fR.
1731 .SS "PCSHOLD"
1755 .sp
1732 .LP
1733 Set the set of held signals for the specific or representative lwp (signals
1734 whose delivery will be blocked if sent to the lwp). The set of signals is
1735 specified with a \fBsigset_t\fR operand. \fBSIGKILL\fR and \fBSIGSTOP\fR cannot
1736 be held; if specified, they are silently ignored.
1737 .SS "PCSFAULT"
1762 .sp
1738 .LP
1739 Define a set of hardware faults to be traced in the process. On incurring one
1740 of these faults, an lwp stops. The set is defined via the operand
1741 \fBfltset_t\fR structure. Fault names are defined in \fB<sys/fault.h>\fR and
1742 include the following. Some of these may not occur on all processors; there may
1743 be processor-specific faults in addition to these.
1744 .sp

\fB\fBFLTPAGE\fR\fR
.ad
.RS 13n
recoverable page fault
.RE

.sp
.LP
When not traced, a fault normally results in the posting of a signal to the lwp
that incurred the fault. If an lwp stops on a fault, the signal is posted to
the lwp when execution is resumed unless the fault is cleared by \fBPCCFAULT\fR
or by the \fBPRCFAULT\fR option of \fBPCRUN\fR. \fBFLTPAGE\fR is an exception;
no signal is posted. The \fBpr_info\fR field in the \fBlwpstatus\fR structure
identifies the signal to be sent and contains machine-specific information
about the fault.
.SS "PCCFAULT"
.sp
.LP
The current fault, if any, is cleared; the associated signal will not be sent
to the specific or representative lwp.
.SS "PCSENTRY PCSEXIT"
.sp
.LP
These control operations instruct the process's lwps to stop on entry to or
exit from specified system calls. The set of system calls to be traced is
defined via an operand \fBsysset_t\fR structure.
.sp
.LP
When entry to a system call is being traced, an lwp stops after having begun
the call to the system but before the system call arguments have been fetched
from the lwp. When exit from a system call is being traced, an lwp stops on
completion of the system call just prior to checking for signals and returning
to user level. At this point, all return values have been stored into the lwp's
registers.
.sp
.LP
If an lwp is stopped on entry to a system call (\fBPR_SYSENTRY\fR) or when
sleeping in an interruptible system call (\fBPR_ASLEEP\fR is set), it may be
instructed to go directly to system call exit by specifying the \fBPRSABORT\fR
flag in a \fBPCRUN\fR control message. Unless exit from the system call is
being traced, the lwp returns to user level showing \fBEINTR\fR.
.SS "PCWATCH"
.sp
.LP
Set or clear a watched area in the controlled process from a \fBprwatch\fR
structure operand:
.sp
.in +2
.nf
typedef struct prwatch {
    uintptr_t pr_vaddr;  /* virtual address of watched area */
    size_t pr_size;      /* size of watched area in bytes */
    int pr_wflags;       /* watch type flags */
} prwatch_t;
.fi
.in -2

.sp
.LP
\fBpr_vaddr\fR specifies the virtual address of an area of memory to be watched
in the controlled process. \fBpr_size\fR specifies the size of the area, in
```

```
bytes. \fBpr_wflags\fR specifies the type of memory access to be monitored as a
bit-mask of the following flags:
.sp
.ne 2
.na
\fB\fBWA_READ\fR\fR
.ad
.RS 16n
read access
.RE

.sp

\fB\fBWA_TRAPAFTER\fR\fR
.ad
.RS 16n
trap after the instruction completes
.RE

.sp
.LP
If \fBpr_wflags\fR is non-empty, a watched area is established for the virtual
address range specified by \fBpr_vaddr\fR and \fBpr_size\fR. If \fBpr_wflags\fR
is empty, any previously-established watched area starting at the specified
virtual address is cleared; \fBpr_size\fR is ignored.
.sp
.LP
A watchpoint is triggered when an lwp in the traced process makes a memory
reference that covers at least one byte of a watched area and the memory
reference is as specified in \fBpr_wflags\fR. When an lwp triggers a
watchpoint, it incurs a watchpoint trap. If \fBFLTWATCH\fR is being traced, the
lwp stops; otherwise, it is sent a \fBSIGTRAP\fR signal; if \fBSIGTRAP\fR is
being traced and is not blocked, the lwp stops.
.sp
.LP
The watchpoint trap occurs before the instruction completes unless
\fBWA_TRAPAFTER\fR was specified, in which case it occurs after the instruction
completes. If it occurs before completion, the memory is not modified. If it
occurs after completion, the memory is modified (if the access is a write
access).
.sp
.LP
Physical i/o is an exception for watchpoint traps. In this instance, there is
no guarantee that memory before the watched area has already been modified (or
in the case of \fBWA_TRAPAFTER\fR, that the memory following the watched area
has not been modified) when the watchpoint trap occurs and the lwp stops.
.sp
```

```
.LP
\fBpr_info\fR in the \fBlwpstatus\fR structure contains information pertinent
to the watchpoint trap. In particular, the \fBsi_addr\fR field contains the
virtual address of the memory reference that triggered the watchpoint, and the
\fBsi_code\fR field contains one of \fBTRAP_RWATCH\fR, \fBTRAP_WWATCH\fR, or
\fBTRAP_XWATCH\fR, indicating read, write, or execute access, respectively. The
\fBsi_trapafter\fR field is zero unless \fBWA_TRAPAFTER\fR is in effect for
this watched area; non-zero indicates that the current instruction is not the
instruction that incurred the watchpoint trap. The \fBsi_pc\fR field contains
the virtual address of the instruction that incurred the trap.
.sp
.LP
A watchpoint trap may be triggered while executing a system call that makes
reference to the traced process's memory. The lwp that is executing the system
call incurs the watchpoint trap while still in the system call. If it stops as
a result, the \fBlwpstatus\fR structure contains the system call number and its
arguments. If the lwp does not stop, or if it is set running again without
clearing the signal or fault, the system call fails with \fBEFAULT\fR. If
\fBWA_TRAPAFTER\fR was specified, the memory reference will have completed and
the memory will have been modified (if the access was a write access) when the
watchpoint trap occurs.
.sp
.LP
If more than one of \fBWA_READ\fR, \fBWA_WRITE\fR, and \fBWA_EXEC\fR is
specified for a watched area, and a single instruction incurs more than one of
the specified types, only one is reported when the watchpoint trap occurs. The
precedence is \fBWA_EXEC\fR, \fBWA_READ\fR, \fBWA_WRITE\fR (\fBWA_EXEC\fR and
\fBWA_READ\fR take precedence over \fBWA_WRITE\fR), unless \fBWA_TRAPAFTER\fR
was specified, in which case it is \fBWA_WRITE\fR, \fBWA_READ\fR, \fBWA_EXEC\fR
(\fBWA_WRITE\fR takes precedence).
.sp
.LP
\fBPCWATCH\fR fails with \fBEINVAL\fR if an attempt is made to specify
overlapping watched areas or if \fBpr_wflags\fR contains flags other than those
specified above. It fails with \fBENOMEM\fR if an attempt is made to establish
more watched areas than the system can support (the system can support
thousands).
.sp
.LP
The child of a \fBvfork\fR(2) borrows the parent's address space. When a
\fBvfork\fR(2) is executed by a traced process, all watched areas established
for the parent are suspended until the child terminates or performs an
\fBexec\fR(2). Any watched areas established independently in the child are
cancelled when the parent resumes after the child's termination or
\fBexec\fR(2). \fBPCWATCH\fR fails with \fBEBUSY\fR if applied to the parent of
a \fBvfork\fR(2) before the child has terminated or performed an \fBexec\fR(2).
The \fBPR_VFORKP\fR flag is set in the \fBpstatus\fR structure for such a
parent process.
.sp
.LP
Certain accesses of the traced process's address space by the operating system
are immune to watchpoints. The initial construction of a signal stack frame
when a signal is delivered to an lwp will not trigger a watchpoint trap even if
the new frame covers watched areas of the stack. Once the signal handler is
entered, watchpoint traps occur normally. On SPARC based machines, register
window overflow and underflow will not trigger watchpoint traps, even if the
register window save areas cover watched areas of the stack.
.sp
.LP
Watched areas are not inherited by child processes, even if the traced
process's inherit-on-fork mode, \fBPR_FORK\fR, is set (see \fBPCSET\fR, below).
All watched areas are cancelled when the traced process performs a successful
\fBexec\fR(2).
.SS "PCSET PCUNSET"
.sp
.LP
```

```
\fBPCSET\fR sets one or more modes of operation for the traced process.
\fBPCUNSET\fR unsets these modes. The modes to be set or unset are specified by
flags in an operand \fBlong\fR in the control message:
.sp
.ne 2
.na
\fB\fBPR_FORK\fR\fR
.ad
.RS 13n
(inherit-on-fork): When set, the process's tracing flags and its
inherit-on-fork mode are inherited by the child of a \fBfork\fR(2),
\fBfork1\fR(2), or \fBvfork\fR(2). When unset, child processes start with all
tracing flags cleared.
.RE

.sp
.ne 2
.na
\fB\fBPR_RLC\fR\fR
.ad
.RS 13n
(run-on-last-close): When set and the last writable \fB/proc\fR file descriptor
referring to the traced process or any of its lwps is closed, all of the
process's tracing flags and watched areas are cleared, any outstanding stop
directives are canceled, and if any lwps are stopped on events of interest,
they are set running as though \fBPCRUN\fR had been applied to them. When
unset, the process's tracing flags and watched areas are retained and lwps are
not set running on last close.
.RE

.sp
.ne 2
.na
\fB\fBPR_KLC\fR\fR
.ad
.RS 13n
(kill-on-last-close): When set and the last writable \fB/proc\fR file
descriptor referring to the traced process or any of its lwps is closed, the
process is terminated with \fBSIGKILL\fR.
.RE

.sp
.ne 2
.na
\fB\fBPR_ASYNC\fR\fR
.ad
.RS 13n
(asynchronous-stop): When set, a stop on an event of interest by one lwp does
not directly affect any other lwp in the process. When unset and an lwp stops
on an event of interest other than \fBPR_REQUESTED\fR, all other lwps in the
process are directed to stop.
.RE

.sp
.ne 2
.na
\fB\fBPR_MSACCT\fR\fR
.ad
.RS 13n
(microstate accounting): Microstate accounting is now continuously enabled.
This flag is deprecated and no longer has any effect upon microstate
accounting. Applications may toggle this flag; however, microstate accounting
will remain enabled regardless.
.RE

.sp
```

```
.ne 2
.na
\fB\fBPR_MSFORK\fR\fR
.ad
.RS 13n
(inherit microstate accounting): All processes now inherit microstate
accounting, as it is continuously enabled. This flag has been deprecated and
its use no longer has any effect upon the behavior of microstate accounting.
.RE

.sp
.ne 2
.na
\fB\fBPR_BPTADJ\fR\fR
.ad
.RS 13n
(breakpoint trap pc adjustment): On x86-based machines, a breakpoint trap
leaves the program counter (the \fBEIP\fR) referring to the breakpointed
instruction plus one byte. When \fBPR_BPTADJ\fR is set, the system will adjust
the program counter back to the location of the breakpointed instruction when
the lwp stops on a breakpoint. This flag has no effect on SPARC based machines,
where breakpoint traps leave the program counter referring to the breakpointed
instruction.
.RE

.sp
.ne 2
.na
\fB\fBPR_PTRACE\fR\fR
.ad
.RS 13n
(ptrace-compatibility): When set, a stop on an event of interest by the traced
process is reported to the parent of the traced process by \fBwait\fR(3C),
\fBSIGTRAP\fR is sent to the traced process when it executes a successful
\fBexec\fR(2), setuid/setgid flags are not honored for execs performed by the
traced process, any exec of an object file that the traced process cannot read
fails, and the process dies when its parent dies. This mode is deprecated; it
is provided only to allow \fBptrace\fR(3C) to be implemented as a library
function using \fB/proc\fR.
.RE

.sp
.LP
It is an error (\fBEINVAL\fR) to specify flags other than those described above
or to apply these operations to a system process. The current modes are
reported in the \fBpr_flags\fR field of \fB/proc/\fR\fIpid\fR\fB/status\fR and
\fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwp\fR\fB/lwpstatus\fR.
.SS "PCSREG"
.sp
.LP
Set the general registers for the specific or representative lwp according to
the operand \fBprgregset_t\fR structure.
.sp
.LP
On SPARC based systems, only the condition-code bits of the processor-status
register (R_PSR) of SPARC V8 (32-bit) processes can be modified by
\fBPCSREG\fR. Other privileged registers cannot be modified at all.
.sp
.LP
On x86-based systems, only certain bits of the flags register (EFL) can be
modified by \fBPCSREG\fR: these include the condition codes, direction-bit, and
overflow-bit.
.sp
.LP
\fBPCSREG\fR fails with \fBEBUSY\fR if the lwp is not stopped on an event of
interest.
```

```
.SS "PCSVADDR"
.sp
.LP
Set the address at which execution will resume for the specific or
representative lwp from the operand \fBlong\fR. On SPARC based systems, both
%pc and %npc are set, with %npc set to the instruction following the virtual
address. On x86-based systems, only %eip is set. \fBPCSVADDR\fR fails with
\fBEBUSY\fR if the lwp is not stopped on an event of interest.
.SS "PCSFPREG"
.sp
.LP
Set the floating-point registers for the specific or representative lwp
according to the operand \fBprfpregset_t\fR structure. An error (\fBEINVAL\fR)
is returned if the system does not support floating-point operations (no
floating-point hardware and the system does not emulate floating-point machine
instructions). \fBPCSFPREG\fR fails with \fBEBUSY\fR if the lwp is not stopped
on an event of interest.
.SS "PCSXREG"
.sp
.LP
Set the extra state registers for the specific or representative lwp according
to the architecture-dependent operand \fBprxregset_t\fR structure. An error
(\fBEINVAL\fR) is returned if the system does not support extra state
registers. \fBPCSXREG\fR fails with \fBEBUSY\fR if the lwp is not stopped on an
event of interest.
.SS "PCSASRS"
.sp
.LP
Set the ancillary state registers for the specific or representative lwp
according to the SPARC V9 platform-dependent operand \fBasrset_t\fR structure.
An error (\fBEINVAL\fR) is returned if either the target process or the
controlling process is not a 64-bit SPARC V9 process. Most of the ancillary
state registers are privileged registers that cannot be modified. Only those
that can be modified are set; all others are silently ignored. \fBPCSASRS\fR
fails with \fBEBUSY\fR if the lwp is not stopped on an event of interest.
.SS "PCAGENT"
.sp
.LP
Create an agent lwp in the controlled process with register values from the
operand \fBprgregset_t\fR structure (see \fBPCSREG\fR, above). The agent lwp is
created in the stopped state showing \fBPR_REQUESTED\fR and with its held
signal set (the signal mask) having all signals except \fBSIGKILL\fR and
\fBSIGSTOP\fR blocked.
.sp
.LP
The \fBPCAGENT\fR operation fails with \fBEBUSY\fR unless the process is fully
stopped via \fB/proc\fR, that is, unless all of the lwps in the process are
stopped either on events of interest or on \fBPR_SUSPENDED\fR, or are stopped
on \fBPR_JOBCONTROL\fR and have been directed to stop via \fBPCDSTOP\fR.  It
fails with \fBEBUSY\fR if an agent lwp already exists. It fails with
\fBENOMEM\fR if system resources for creating new lwps have been exhausted.
.sp
.LP
Any \fBPCRUN\fR operation applied to the process control file or to the control
file of an lwp other than the agent lwp fails with \fBEBUSY\fR as long as the
agent lwp exists. The agent lwp must be caused to terminate by executing the
\fBSYS_lwp_exit\fR system call trap before the process can be restarted.
.sp
.LP
Once the agent lwp is created, its lwp-ID can be found by reading the process
status file. To facilitate opening the agent lwp's control and status files,
the directory name \fB/propc/\fR\fIpid\fR\fB/lwp/agent\fR is accepted for
lookup operations as an invisible alias for
\fB/proc/\fR\fIpid\fR\fB/lwp/\fR\fIlwpid,\fR \fIlwpid\fR being the lwp-ID of
the agent lwp (invisible in the sense that the name ''agent'' does not appear
in a directory listing of \fB/proc/\fR\fIpid\fR\fB/lwp\fR obtained from
```

\fBls\fR(1), \fBgetdents\fR(2), or \fBreaddir\fR(3C)).
.sp
.LP
The purpose of the agent lwp is to perform operations in the controlled process on behalf of the controlling process: to gather information not directly available via \fB/proc\fR files, or in general to make the process change state in ways not directly available via \fB/proc\fR control operations. To make use of an agent lwp, the controlling process must be capable of making it execute system calls (specifically, the \fBSYS_lwp_exit\fR system call trap). The register values given to the agent lwp on creation are typically the registers of the representative lwp, so that the agent lwp can use its stack.
.sp
.LP
If the controlling process neglects to force the agent lwp to execute the \fBSYS_lwp_exit\fR system call (due to either logic error or fatal failure on the part of the controlling process), the agent lwp will remain in the target process. For purposes of being able to debug these otherwise rogue agents, information as to the creator of the agent lwp is reflected in that lwp's \fBspymaster\fR file in \fB/proc\fR. Should the target process generate a core dump with the agent lwp in place, this information will be available via the \fBNT_SPYMASTER\fR note in the core file (see \fBcore\fR(4)).
.sp
.LP
The agent lwp is not allowed to execute any variation of the \fBSYS_fork\fR or \fBSYS_exec\fR system call traps. Attempts to do so yield \fBENOTSUP\fR to the agent lwp.
.sp
.LP
Symbolic constants for system call trap numbers like \fBSYS_lwp_exit\fR and \fBSYS_lwp_create\fR can be found in the header file <\fBsys/syscall.h\fR>.
.SS "PCREAD PCWRITE"
.sp
.LP
Read or write the target process's address space via a \fBpriovec\fR structure operand:
.sp
.in +2
.nf
typedef struct priovec {
    void *pio_base;   /* buffer in controlling process */
    size_t pio_len;   /* size of read/write request in bytes */
    off_t pio_offset;   /* virtual address in target process */
} priovec_t;
.fi
.in -2

.sp
.LP
These operations have the same effect as \fBpread\fR(2) and \fBpwrite\fR(2), respectively, of the target process's address space file. The difference is that more than one \fBPCREAD\fR or \fBPCWRITE\fR control operation can be written to the control file at once, and they can be interspersed with other control operations in a single write to the control file. This is useful, for example, when planting many breakpoint instructions in the process's address space, or when stepping over a breakpointed instruction. Unlike \fBpread\fR(2) and \fBpwrite\fR(2), no provision is made for partial reads or writes; if the operation cannot be performed completely, it fails with \fBEIO\fR.
.SS "PCNICE"
.sp
.LP
The traced process's \fBnice\fR(2) value is incremented by the amount in the operand \fBlong\fR. Only a process with the {\fBPRIV_PROC_PRIOCNTL\fR} privilege asserted in its effective set can better a process's priority in this way, but any user may lower the priority. This operation is not meaningful for all scheduling classes.
.SS "PCSCRED"

.sp
.LP
Set the target process credentials to the values contained in the \fBprcred_t\fR structure operand (see \fB/proc/\fR\fIpid\fR\fB/cred\fR). The effective, real, and saved user-IDs and group-IDs of the target process are set. The target process's supplementary groups are not changed; the \fBpr_ngroups\fR and \fBpr_groups\fR members of the structure operand are ignored. Only the privileged processes can perform this operation; for all others it fails with \fBEPERM\fR.
.SS "PCSCREDX"
.sp
.LP
Operates like \fBPCSCRED\fR but also sets the supplementary groups; the length of the data written with this control operation should be "sizeof (\fBprcred_t\fR) + sizeof (\fBgid_t)\fR * (#groups - 1)".
.SS "PCSPRIV"
.sp
.LP
Set the target process privilege to the values contained in the \fBprpriv_t\fR operand (see \fB/proc/pid/priv\fR). The effective, permitted, inheritable, and limit sets are all changed. Privilege flags can also be set. The process is made privilege aware unless it can relinquish privilege awareness. See \fBprivileges\fR(5).
.sp
.LP
The limit set of the target process cannot be grown. The other privilege sets must be subsets of the intersection of the effective set of the calling process with the new limit set of the target process or subsets of the original values of the sets in the target process.
.sp
.LP
If any of the above restrictions are not met, \fBEPERM\fR is returned. If the structure written is improperly formatted, \fBEINVAL\fR is returned.
.SH PROGRAMMING NOTES
.sp
.LP
For security reasons, except for the \fBpsinfo\fR, \fBusage\fR, \fBlpsinfo\fR, \fBlusage\fR, \fBlwpsinfo\fR, and \fBlwpusage\fR files, which are world-readable, and except for privileged processes, an open of a \fB/proc\fR file fails unless both the user-ID and group-ID of the caller match those of the traced process and the process's object file is readable by the caller. The effective set of the caller is a superset of both the inheritable and the permitted set of the target process. The limit set of the caller is a superset of the limit set of the target process. Except for the world-readable files just mentioned, files corresponding to setuid and setgid processes can be opened only by the appropriately privileged process.
.sp
.LP
A process that is missing the basic privilege {\fBPRIV_PROC_INFO\fR} cannot see any processes under \fB/proc\fR that it cannot send a signal to.
.sp
.LP
A process that has {\fBPRIV_PROC_OWNER\fR} asserted in its effective set can open any file for reading. To manipulate or control a process, the controlling process must have at least as many privileges in its effective set as the target process has in its effective, inheritable, and permitted sets. The limit set of the controlling process must be a superset of the limit set of the target process. Additional restrictions apply if any of the uids of the target process are 0. See \fBprivileges\fR(5).
.sp
.LP
Even if held by a privileged process, an open process or lwp file descriptor (other than file descriptors for the world-readable files) becomes invalid if the traced process performs an \fBexec\fR(2) of a setuid/setgid object file or an object file that the traced process cannot read. Any operation performed on an invalid file descriptor, except \fBclose\fR(2), fails with \fBEAGAIN\fR. In

this situation, if any tracing flags are set and the process or any lwp file descriptor is open for writing, the process will have been directed to stop and its run-on-last-close flag will have been set (see \fBPCSET\fR). This enables a controlling process (if it has permission) to reopen the \fB/proc\fR files to get new valid file descriptors, close the invalid file descriptors, unset the run-on-last-close flag (if desired), and proceed. Just closing the invalid file descriptors causes the traced process to resume execution with all tracing flags cleared. Any process not currently open for writing via \fB/proc\fR, but that has left-over tracing flags from a previous open, and that executes a setuid/setgid or unreadable object file, will not be stopped but will have all its tracing flags cleared.
.sp
.LP
To wait for one or more of a set of processes or lwps to stop or terminate, \fB/proc\fR file descriptors (other than those obtained by opening the \fBcwd\fR or \fBroot\fR directories or by opening files in the \fBfd\fR or \fBobject\fR directories) can be used in a \fBpoll\fR(2) system call. When requested and returned, either of the polling events \fBPOLLPRI\fR or \fBPOLLWRNORM\fR indicates that the process or lwp stopped on an event of interest. Although they cannot be requested, the polling events \fBPOLLHUP\fR, \fBPOLLERR\fR, and \fBPOLLNVAL\fR may be returned. \fBPOLLHUP\fR indicates that the process or lwp has terminated. \fBPOLLERR\fR indicates that the file descriptor has become invalid. \fBPOLLNVAL\fR is returned immediately if \fBPOLLPRI\fR or \fBPOLLWRNORM\fR is requested on a file descriptor referring to a system process (see \fBPCSTOP\fR). The requested events may be empty to wait simply for termination.

2794 .SH DIAGNOSTICS
2838 .sp
2795 .LP
2796 Errors that can occur in addition to the errors normally associated with file
2797 system access:
2798 .sp
2799 .ne 2
2800 .na
2801 \fB\fBE2BIG\fR\fR
2802 .ad
2803 .RS 13n
2804 Data to be returned in a \fBread\fR(2) of the page data file exceeds the size
2805 of the read buffer provided by the caller.
2806 .RE

2808 .sp
2809 .ne 2
2810 .na
```

```
2811 \fB\fBEACCES\fR\fR
2812 .ad
2813 .RS 13n
2814 An attempt was made to examine a process that ran under a different uid than
2815 the controlling process and {\fBPRIV_PROC_OWNER\fR} was not asserted in the
2816 effective set.
2817 .RE

2819 .sp
2820 .ne 2
2821 .na
2822 \fB\fBEAGAIN\fR\fR
2823 .ad
2824 .RS 13n
2825 The traced process has performed an \fBexec\fR(2) of a setuid/setgid object
2826 file or of an object file that it cannot read; all further operations on the
2827 process or lwp file descriptor (except \fBclose\fR(2)) elicit this error.
2828 .RE

2830 .sp
2831 .ne 2
2832 .na
2833 \fB\fBEBUSY\fR\fR
2834 .ad
2835 .RS 13n
2836 \fBPCSTOP\fR, \fBPCDSTOP\fR, \fBPCWSTOP\fR, or \fBPCTWSTOP\fR was applied to a
2837 system process; an exclusive \fBopen\fR(2) was attempted on a \fB/proc\fR file
2838 for a process already open for writing; \fBPCRUN\fR, \fBPCSREG\fR,
2839 \fBPCSVADDR\fR, \fBPCSFPREG\fR, or \fBPCSXREG\fR was applied to a process or
2840 lwp not stopped on an event of interest; an attempt was made to mount
2841 \fB/proc\fR when it was already mounted; \fBPCAGENT\fR was applied to a process
2842 that was not fully stopped or that already had an agent lwp.
2843 .RE

2845 .sp
2846 .ne 2
2847 .na
2848 \fB\fBEINVAL\fR\fR
2849 .ad
2850 .RS 13n
2851 In general, this means that some invalid argument was supplied to a system
2852 call. A non-exhaustive list of conditions eliciting this error includes: a
2853 control message operation code is undefined; an out-of-range signal number was
2854 specified with \fBPCSSIG\fR, \fBPCKILL\fR, or \fBPCUNKILL\fR; \fBSIGKILL\fR was
2855 specified with \fBPCUNKILL\fR; \fBPCSFPREG\fR was applied on a system that does
2856 not support floating-point operations; \fBPCSXREG\fR was applied on a system
2857 that does not support extra state registers.
2858 .RE

2860 .sp
2861 .ne 2
2862 .na
2863 \fB\fBEINTR\fR\fR
2864 .ad
2865 .RS 13n
2866 A signal was received by the controlling process while waiting for the traced
2867 process or lwp to stop via \fBPCSTOP\fR, \fBPCWSTOP\fR, or \fBPCTWSTOP\fR.
2868 .RE

2870 .sp
2871 .ne 2
2872 .na
2873 \fB\fBEIO\fR\fR
2874 .ad
2875 .RS 13n
2876 A \fBwrite\fR(2) was attempted at an illegal address in the traced process.
```

```
.RE

.sp
.ne 2
.na
\fB\fBENOENT\fR\fR
.ad
.RS 13n
The traced process or lwp has terminated after being opened. The basic
privilege {\fBPRIV_PROC_INFO\fR} is not asserted in the effective set of the
calling process and the calling process cannot send a signal to the target
process.
.RE

.sp
.ne 2
.na
\fB\fBENOMEM\fR\fR
.ad
.RS 13n
The system-imposed limit on the number of page data file descriptors was
reached on an open of \fB/proc/\fR\fIpid\fR\fB/pagedata\fR; an attempt was made
with \fBPCWATCH\fR to establish more watched areas than the system can support;
the \fBPCAGENT\fR operation was issued when the system was out of resources for
creating lwps.
.RE

.sp
.ne 2
.na
\fB\fBENOSYS\fR\fR
.ad
.RS 13n
An attempt was made to perform an unsupported operation (such as
\fBcreat\fR(2), \fBlink\fR(2), or \fBunlink\fR(2)) on an entry in \fB/proc\fR.
.RE

.sp
.ne 2
.na
\fB\fBEOVERFLOW\fR\fR
.ad
.RS 13n
A 32-bit controlling process attempted to read or write the \fBas\fR file or
attempted to read the \fBmap\fR, \fBrmap\fR, or \fBpagedata\fR file of a 64-bit
target process. A 32-bit controlling process attempted to apply one of the
control operations \fBPCSREG\fR, \fBPCSXREG\fR, \fBPCSVADDR\fR, \fBPCWATCH\fR,
\fBPCAGENT\fR, \fBPCREAD\fR, \fBPCWRITE\fR to a 64-bit target process.
.RE

.sp
.ne 2
.na
\fB\fBEPERM\fR\fR
.ad
.RS 13n
The process that issued the \fBPCSCRED\fR or \fBPCSCREDX\fR operation did not
have the {\fBPRIV_PROC_SETID\fR} privilege asserted in its effective set, or
the process that issued the \fBPCNICE\fR operation did not have the
{\fBPRIV_PROC_PRIOCNTL\fR} in its effective set.
.sp
An attempt was made to control a process of which the E, P, and I privilege
sets were not a subset of the effective set of the controlling process or the
limit set of the controlling process is not a superset of limit set of the
controlled process.
.sp
```

```
Any of the uids of the target process are 0 or an attempt was made to change
any of the uids to 0 using PCSCRED and the security policy imposed additional
restrictions. See \fBprivileges\fR(5).
.RE

.SH NOTES
.sp
.LP
Descriptions of structures in this document include only interesting structure
elements, not filler and padding fields, and may show elements out of order for
descriptive clarity. The actual structure definitions are contained in
\fB<procfs.h>\fR\&.
.SH BUGS
.sp
.LP
Because the old \fBioctl\fR(2)-based version of \fB/proc\fR is currently
supported for binary compatibility with old applications, the top-level
directory for a process, \fB/proc/\fR\fIpid\fR, is not world-readable, but it
is world-searchable. Thus, anyone can open \fB/proc/\fR\fIpid\fR\fB/psinfo\fR
even though \fBls\fR(1) applied to \fB/proc/\fR\fIpid\fR will fail for anyone
but the owner or an appropriately privileged process. Support for the old
\fBioctl\fR(2)-based version of \fB/proc\fR will be dropped in a future
release, at which time the top-level directory for a process will be made
world-readable.
.sp
.LP
On SPARC based machines, the types \fBgregset_t\fR and \fBfpregset_t\fR defined
in <\fBsys/regset.h\fR> are similar to but not the same as the types
\fBprgregset_t\fR and \fBprfpregset_t\fR defined in <\fBprocfs.h\fR>.
```

```

   7 .TH PRIVILEGES 5 "Jun 6, 2016"
   7 .TH PRIVILEGES 5 "Oct 30, 2015"
   8 .SH NAME
   9 privileges \- process privilege model
  10 .SH DESCRIPTION
  11 .LP
  12 Solaris software implements a set of privileges that provide fine-grained
  13 control over the actions of processes. The possession of a certain privilege
  14 allows a process to perform a specific set of restricted operations.
  15 .sp
  16 .LP
  17 The change to a primarily privilege-based security model in the Solaris
  18 operating system gives developers an opportunity to restrict processes to those
  19 privileged operations actually needed instead of all (super-user) or no
  20 privileges (non-zero UIDs). Additionally, a set of previously unrestricted
  21 operations now requires a privilege; these privileges are dubbed the "basic"
  22 privileges and are by default given to all processes.
  23 .sp
  24 .LP
  25 Taken together, all defined privileges with the exception of the "basic"
  26 privileges compose the set of privileges that are traditionally associated with
  27 the root user. The "basic" privileges are "privileges" unprivileged processes
  28 were accustomed to having.
  29 .sp
  30 .LP
  31 The defined privileges are:
  32 .sp
  33 .ne 2
  34 .na
  35 \fB\fBPRIV_CONTRACT_EVENT\fR\fR
  36 .ad
  37 .sp .6
  38 .RS 4n
  39 Allow a process to request reliable delivery of events to an event endpoint.
  40 .sp
  41 Allow a process to include events in the critical event set term of a template
  42 which could be generated in volume by the user.
  43 .RE

  45 .sp
  46 .ne 2
  47 .na
  48 \fB\fBPRIV_CONTRACT_IDENTITY\fR\fR
  49 .ad
  50 .sp .6
  51 .RS 4n
  52 Allows a process to set the service FMRI value of a process contract template.
  53 .RE

  55 .sp
  56 .ne 2
```

```
  57 .na
  58 \fB\fBPRIV_CONTRACT_OBSERVER\fR\fR
  59 .ad
  60 .sp .6
  61 .RS 4n
  62 Allow a process to observe contract events generated by contracts created and
  63 owned by users other than the process's effective user ID.
  64 .sp
  65 Allow a process to open contract event endpoints belonging to contracts created
  66 and owned by users other than the process's effective user ID.
  67 .RE

  69 .sp
  70 .ne 2
  71 .na
  72 \fB\fBPRIV_CPC_CPU\fR\fR
  73 .ad
  74 .sp .6
  75 .RS 4n
  76 Allow a process to access per-CPU hardware performance counters.
  77 .RE

  79 .sp
  80 .ne 2
  81 .na
  82 \fB\fBPRIV_DTRACE_KERNEL\fR\fR
  83 .ad
  84 .sp .6
  85 .RS 4n
  86 Allow DTrace kernel-level tracing.
  87 .RE

  89 .sp
  90 .ne 2
  91 .na
  92 \fB\fBPRIV_DTRACE_PROC\fR\fR
  93 .ad
  94 .sp .6
  95 .RS 4n
  96 Allow DTrace process-level tracing. Allow process-level tracing probes to be
  97 placed and enabled in processes to which the user has permissions.
  98 .RE

 100 .sp
 101 .ne 2
 102 .na
 103 \fB\fBPRIV_DTRACE_USER\fR\fR
 104 .ad
 105 .sp .6
 106 .RS 4n
 107 Allow DTrace user-level tracing. Allow use of the syscall and profile DTrace
 108 providers to examine processes to which the user has permissions.
 109 .RE

 111 .sp
 112 .ne 2
 113 .na
 114 \fB\fBPRIV_FILE_CHOWN\fR\fR
 115 .ad
 116 .sp .6
 117 .RS 4n
 118 Allow a process to change a file's owner user ID. Allow a process to change a
 119 file's group ID to one other than the process's effective group ID or one of
 120 the process's supplemental group IDs.
 121 .RE
```

```
.sp
.ne 2
.na
\fB\fBPRIV_FILE_CHOWN_SELF\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to give away its files. A process with this privilege runs as
if {\fB_POSIX_CHOWN_RESTRICTED\fR} is not in effect.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_DAC_EXECUTE\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to execute an executable file whose permission bits or ACL
would otherwise disallow the process execute permission.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_DAC_READ\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to read a file or directory whose permission bits or ACL would
otherwise disallow the process read permission.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_DAC_SEARCH\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to search a directory whose permission bits or ACL would not
otherwise allow the process search permission.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_DAC_WRITE\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to write a file or directory whose permission bits or ACL do
not allow the process write permission. All privileges are required to write
files owned by UID 0 in the absence of an effective UID of 0.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_DOWNGRADE_SL\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to set the sensitivity label of a file or directory to a
sensitivity label that does not dominate the existing sensitivity label.
.sp
```

```
This privilege is interpreted only if the system is configured with Trusted
Extensions.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_FLAG_SET\fR\fR
.ad
.sp .6
.RS 4n
Allows a process to set immutable, nounlink or appendonly file attributes.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_LINK_ANY\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to create hardlinks to files owned by a UID different from the
process's effective UID.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_OWNER\fR\fR
.ad
.sp .6
.RS 4n
Allow a process that is not the owner of a file to modify that file's access
and modification times. Allow a process that is not the owner of a directory to
modify that directory's access and modification times. Allow a process that is
not the owner of a file or directory to remove or rename a file or directory
whose parent directory has the "save text image after execution" (sticky) bit
set. Allow a process that is not the owner of a file to mount a \fBnamefs\fR
upon that file. Allow a process that is not the owner of a file or directory to
modify that file's or directory's permission bits or ACL.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_READ\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to open objects in the filesystem for reading. This
privilege is not necessary to read from an already open file which was opened
before dropping the \fBPRIV_FILE_READ\fR privilege.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_FILE_SETID\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to change the ownership of a file or write to a file without
the set-user-ID and set-group-ID bits being cleared. Allow a process to set the
set-group-ID bit on a file or directory whose group is not the process's
effective group or one of the process's supplemental groups. Allow a process to
set the set-user-ID bit on a file with different ownership in the presence of
```

```
255 \fBPRIV_FILE_OWNER\fR. Additional restrictions apply when creating or modifying
256 a setuid 0 file.
257 .RE

259 .sp
260 .ne 2
261 .na
262 \fB\fBPRIV_FILE_UPGRADE_SL\fR\fR
263 .ad
264 .sp .6
265 .RS 4n
266 Allow a process to set the sensitivity label of a file or directory to a
267 sensitivity label that dominates the existing sensitivity label.
268 .sp
269 This privilege is interpreted only if the system is configured with Trusted
270 Extensions.
271 .RE

273 .sp
274 .ne 2
275 .na
276 \fB\fBPRIV_FILE_WRITE\fR\fR
277 .ad
278 .sp .6
279 .RS 4n
280 Allow a process to open objects in the filesytem for writing, or otherwise
281 modify them. This privilege is not necessary to write to an already open file
282 which was opened before dropping the \fBPRIV_FILE_WRITE\fR privilege.
283 .RE

285 .sp
286 .ne 2
287 .na
288 \fB\fBPRIV_GRAPHICS_ACCESS\fR\fR
289 .ad
290 .sp .6
291 .RS 4n
292 Allow a process to make privileged ioctls to graphics devices. Typically only
293 an xserver process needs to have this privilege. A process with this privilege
294 is also allowed to perform privileged graphics device mappings.
295 .RE

297 .sp
298 .ne 2
299 .na
300 \fB\fBPRIV_GRAPHICS_MAP\fR\fR
301 .ad
302 .sp .6
303 .RS 4n
304 Allow a process to perform privileged mappings through a graphics device.
305 .RE

307 .sp
308 .ne 2
309 .na
310 \fB\fBPRIV_IPC_DAC_READ\fR\fR
311 .ad
312 .sp .6
313 .RS 4n
314 Allow a process to read a System V IPC Message Queue, Semaphore Set, or Shared
315 Memory Segment whose permission bits would not otherwise allow the process read
316 permission.
317 .RE

319 .sp
320 .ne 2
```

```
321 .na
322 \fB\fBPRIV_IPC_DAC_WRITE\fR\fR
323 .ad
324 .sp .6
325 .RS 4n
326 Allow a process to write a System V IPC Message Queue, Semaphore Set, or Shared
327 Memory Segment whose permission bits would not otherwise allow the process
328 write permission.
329 .RE

331 .sp
332 .ne 2
333 .na
334 \fB\fBPRIV_IPC_OWNER\fR\fR
335 .ad
336 .sp .6
337 .RS 4n
338 Allow a process that is not the owner of a System V IPC Message Queue,
339 Semaphore Set, or Shared Memory Segment to remove, change ownership of, or
340 change permission bits of the Message Queue, Semaphore Set, or Shared Memory
341 Segment.
342 .RE

344 .sp
345 .ne 2
346 .na
347 \fB\fBPRIV_NET_ACCESS\fR\fR
348 .ad
349 .sp .6
350 .RS 4n
351 Allow a process to open a TCP, UDP, SDP, or SCTP network endpoint. This
352 privilege is not necessary to communicate using an existing endpoint already
353 opened before dropping the \fBPRIV_NET_ACCESS\fR privilege.
354 .RE

356 .sp
357 .ne 2
358 .na
359 \fB\fBPRIV_NET_BINDMLP\fR\fR
360 .ad
361 .sp .6
362 .RS 4n
363 Allow a process to bind to a port that is configured as a multi-level port
364 (MLP) for the process’s zone. This privilege applies to both shared address and
365 zone-specific address MLPs. See \fBtnzonecfg\fR(\fB4\fR) from the Trusted
366 Extensions manual pages for information on configuring MLP ports.
367 .sp
368 This privilege is interpreted only if the system is configured with Trusted
369 Extensions.
370 .RE

372 .sp
373 .ne 2
374 .na
375 \fB\fBPRIV_NET_ICMPACCESS\fR\fR
376 .ad
377 .sp .6
378 .RS 4n
379 Allow a process to send and receive ICMP packets.
380 .RE

382 .sp
383 .ne 2
384 .na
385 \fB\fBPRIV_NET_MAC_AWARE\fR\fR
386 .ad
```

```
.sp .6
.RS 4n
Allow a process to set the \fBNET_MAC_AWARE\fR process flag by using
\fBsetpflags\fR(2). This privilege also allows a process to set the
\fBSO_MAC_EXEMPT\fR socket option by using \fBsetsockopt\fR(3SOCKET). The
\fBNET_MAC_AWARE\fR process flag and the \fBSO_MAC_EXEMPT\fR socket option both
allow a local process to communicate with an unlabeled peer if the local
process's label dominates the peer's default label, or if the local process
runs in the global zone.
.sp
This privilege is interpreted only if the system is configured with Trusted
Extensions.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_NET_MAC_IMPLICIT\fR\fR
.ad
.sp .6
.RS 4n
Allow a proces to set \fBSO_MAC_IMPLICIT\fR option by using
\fBsetsockopt\fR(3SOCKET).  This allows a privileged process to transmit
implicitly-labeled packets to a peer.
.sp
This privilege is interpreted only if the system is configured with
Trusted Extensions.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_NET_OBSERVABILITY\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to open a device for just receiving network traffic, sending
traffic is disallowed.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_NET_PRIVADDR\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to bind to a privileged port number. The privilege port numbers
are 1-1023 (the traditional UNIX privileged ports) as well as those ports
marked as "\fBudp/tcp_extra_priv_ports\fR" with the exception of the ports
reserved for use by NFS and SMB.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_NET_RAWACCESS\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to have direct access to the network layer.
.RE

.sp
.ne 2
.na
```

```
\fB\fBPRIV_PROC_AUDIT\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to generate audit records. Allow a process to get its own audit
pre-selection information.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_CHROOT\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to change its root directory.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_CLOCK_HIGHRES\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to use high resolution timers.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_EXEC\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to call \fBexec\fR(2).
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_FORK\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to call \fBfork\fR(2), \fBfork1\fR(2), or \fBvfork\fR(2).
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_INFO\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to examine the status of processes other than those to which it
can send signals. Processes that cannot be examined cannot be seen in
\fB/proc\fR and appear not to exist.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_LOCK_MEMORY\fR\fR
.ad
.sp .6
```

```
.RS 4n
Allow a process to lock pages in physical memory.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_MEMINFO\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to access physical memory information.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_PROC_OWNER\fR\fR
.ad
.sp .6
.RS 4n
Allow a process to send signals to other processes and inspect and modify the
process state in other processes, regardless of ownership. When modifying
another process, additional restrictions apply: the effective privilege set of
the attaching process must be a superset of the target process's effective,
permitted, and inheritable sets; the limit set must be a superset of the
target's limit set; if the target process has any UID set to 0 all privilege
must be asserted unless the effective UID is 0. Allow a process to bind
arbitrary processes to CPUs.

This privilege is interpreted only if the system is configured with Trusted
Extensions.
.RE

.sp
.ne 2
.na
\fB\fBPRIV_XVM_CONTROL\fR\fR
.ad
.sp .6
.RS 4n
Allows a process access to the \fBxVM\fR(5) control devices for managing guest
domains and the hypervisor. This privilege is used only if booted into xVM on
x86 platforms.
.RE

.sp
.LP
Of the privileges listed above, the privileges \fBPRIV_FILE_LINK_ANY\fR,
\fBPRIV_PROC_INFO\fR, \fBPRIV_PROC_SESSION\fR, \fBPRIV_PROC_FORK\fR,
\fBPRIV_FILE_READ\fR, \fBPRIV_FILE_WRITE\fR, \fBPRIV_NET_ACCESS\fR and
\fBPRIV_PROC_EXEC\fR are considered "basic" privileges. These are privileges
that used to be always available to unprivileged processes. By default,
processes still have the basic privileges.
.sp
.LP
The privileges \fBPRIV_PROC_SETID\fR and \fBPRIV_PROC_AUDIT\fR must be present
in the Limit set (see below) of a process in order for set-uid root \fBexec\fRs
to be successful, that is, get an effective UID of 0 and additional privileges.
.sp
.LP
The privilege implementation in Solaris extends the process credential with
four privilege sets:
.sp
.ne 2
.na
\fBI, the inheritable set\fR
.ad
.RS 26n
The privileges inherited on \fBexec\fR.
.RE

.sp
.ne 2
```

```
.na
\fBP, the permitted set\fR
.ad
.RS 26n
The maximum set of privileges for the process.
.RE

.sp
.ne 2
.na
\fBE, the effective set\fR
.ad
.RS 26n
The privileges currently in effect.
.RE

.sp
.ne 2
.na
\fBL, the limit set\fR
.ad
.RS 26n
The upper bound of the privileges a process and its offspring can obtain.
Changes to L take effect on the next \fBexec\fR.
.RE

.sp
.LP
The sets I, P and E are typically identical to the basic set of privileges for
unprivileged processes. The limit set is typically the full set of privileges.
.sp
.LP
Each process has a Privilege Awareness State (PAS) that can take the value PA
(privilege-aware) and NPA (not-PA). PAS is a transitional mechanism that allows
a choice between full compatibility with the old superuser model and completely
ignoring the effective UID.
.sp
.LP
To facilitate the discussion, we introduce the notion of "observed effective
set" (oE) and "observed permitted set" (oP) and the implementation sets iE and
iP.
.sp
.LP
A process becomes privilege-aware either by manipulating the effective,
permitted, or limit privilege sets through \fBsetppriv\fR(2) or by using
\fBsetpflags\fR(2). In all cases, oE and oP are invariant in the process of
becoming privilege-aware. In the process of becoming privilege-aware, the
following assignments take place:
.sp
.in +2
.nf
iE = oE
iP = oP
.fi
.in -2

.sp
.LP
When a process is privilege-aware, oE and oP are invariant under UID changes.
When a process is not privilege-aware, oE and oP are observed as follows:
.sp
.in +2
.nf
oE = euid == 0 ? L : iE
oP = (euid == 0 || ruid == 0 || suid == 0) ? L : iP
.fi
```

```
.in -2

.sp
.LP
When a non-privilege-aware process has an effective UID of 0, it can exercise
the privileges contained in its limit set, the upper bound of its privileges.
If a non-privilege-aware process has any of the UIDs 0, it appears to be
capable of potentially exercising all privileges in L.
.sp
.LP
It is possible for a process to return to the non-privilege aware state using
\fBsetpflags()\fR. The kernel always attempts this on \fBexec\fR(2). This
operation is permitted only if the following conditions are met:
.RS +4
.TP
.ie t \(bu
.el o
If any of the UIDs is equal to 0, P must be equal to L.
.RE
.RS +4
.TP
.ie t \(bu
.el o
If the effective UID is equal to 0, E must be equal to L.
.RE
.sp
.LP
When a process gives up privilege awareness, the following assignments take
place:
.sp
.in +2
.nf
if (euid == 0) iE = L & I
if (any uid == 0) iP = L & I
.fi
.in -2

.sp
.LP
The privileges obtained when not having a UID of \fB0\fR are the inheritable
set of the process restricted by the limit set.
.sp
.LP
Only privileges in the process's (observed) effective privilege set allow the
process to perform restricted operations. A process can use any of the
privilege manipulation functions to add or remove privileges from the privilege
sets. Privileges can be removed always. Only privileges found in the permitted
set can be added to the effective and inheritable set. The limit set cannot
grow. The inheritable set can be larger than the permitted set.
.sp
.LP
When a process performs an \fBexec\fR(2), the kernel first tries to relinquish
privilege awareness before making the following privilege set modifications:
.sp
.in +2
.nf
E' = P' = I' = L & I
L is unchanged
.fi
.in -2

.sp
.LP
If a process has not manipulated its privileges, the privilege sets effectively
remain the same, as E, P and I are already identical.
.sp
```

```
.LP
The limit set is enforced at \fBexec\fR time.
.sp
.LP
To run a non-privilege-aware application in a backward-compatible manner, a
privilege-aware application should start the non-privilege-aware application
with I=basic.
.sp
.LP
For most privileges, absence of the privilege simply results in a failure. In
some instances, the absense of a privilege can cause system calls to behave
differently. In other instances, the removal of a privilege can force a set-uid
application to seriously malfunction. Privileges of this type are considered
"unsafe". When a process is lacking any of the unsafe privileges from its limit
set, the system does not honor the set-uid bit of set-uid root applications.
The following unsafe privileges have been identified: \fBproc_setid\fR,
\fBsys_resource\fR and \fBproc_audit\fR.
.SS "Privilege Escalation"
.LP
In certain circumstances, a single privilege could lead to a process gaining
one or more additional privileges that were not explicitly granted to that
process. To prevent such an escalation of privileges, the security policy
requires explicit permission for those additional privileges.
.sp
.LP
Common examples of escalation are those mechanisms that allow modification of
system resources through "raw'' interfaces; for example, changing kernel data
structures through \fB/dev/kmem\fR or changing files through \fB/dev/dsk/*\fR.
Escalation also occurs when a process controls processes with more privileges
than the controlling process. A special case of this is manipulating or
creating objects owned by UID 0 or trying to obtain UID 0 using
\fBsetuid\fR(2). The special treatment of UID 0 is needed because the UID 0
owns all system configuration files and ordinary file protection mechanisms
allow processes with UID 0 to modify the system configuration. With appropriate
file modifications, a given process running with an effective UID of 0 can gain
all privileges.
.sp
.LP
In situations where a process might obtain UID 0, the security policy requires
additional privileges, up to the full set of privileges. Such restrictions
could be relaxed or removed at such time as additional mechanisms for
protection of system files became available. There are no such mechanisms in
the current Solaris release.
.sp
.LP
The use of UID 0 processes should be limited as much as possible. They should
be replaced with programs running under a different UID but with exactly the
privileges they need.
.sp
.LP
Daemons that never need to \fBexec\fR subprocesses should remove the
\fBPRIV_PROC_EXEC\fR privilege from their permitted and limit sets.
.SS "Assigned Privileges and Safeguards"
.LP
When privileges are assigned to a user, the system administrator could give
that user more powers than intended. The administrator should consider whether
safeguards are needed. For example, if the \fBPRIV_PROC_LOCK_MEMORY\fR
privilege is given to a user, the administrator should consider setting the
\fBproject.max-locked-memory\fR resource control as well, to prevent that user
from locking all memory.
.SS "Privilege Debugging"
.LP
When a system call fails with a permission error, it is not always immediately
obvious what caused the problem. To debug such a problem, you can use a tool
called \fBprivilege debugging\fR. When privilege debugging is enabled for a
process, the kernel reports missing privileges on the controlling terminal of
```

```
1311 the process. (Enable debugging for a process with the \fB-D\fR option of
1312 \fBppriv\fR(1).) Additionally, the administrator can enable system-wide
1313 privilege debugging by setting the \fBsystem\fR(4) variable \fBpriv_debug\fR
1314 using:
1315 .sp
1316 .in +2
1317 .nf
1318 set priv_debug = 1
1319 .fi
1320 .in -2

1322 .sp
1323 .LP
1324 On a running system, you can use \fBmdb\fR(1) to change this variable.
1325 .SS "Privilege Administration"
1326 .LP
1327 The Solaris Management Console (see \fBsmc\fR(1M)) is the preferred method of
1328 modifying privileges for a command. Use \fBusermod\fR(1M) or \fBsmrole\fR(1M)
1329 to assign privileges to or modify privileges for, respectively, a user or a
1330 role. Use \fBppriv\fR(1) to enumerate the privileges supported on a system and
1331 \fBtruss\fR(1) to determine which privileges a program requires.

.TH "SECURITY-FLAGS" "5" "June 6, 2016"
.SH "NAME"
\fBsecurity-flags\fR - process security flags
.SH "DESCRIPTION"
Each process on an illumos system has an associated set of security-flags
which describe additional per-process security and exploit mitigation
features which are enabled for that process.
.P
There are four sets of these flags for each process, the effective set
(abbreviated \fIE\fR) are the set which currently apply to the process and are
immutable. The inheritable set (abbreviated \fII\fR) are the flags which will
become effective the next time the process calls one of the \fBexec(2)\fR
family of functions, and will be inherited as both the effective and
inheritable sets by any child processes. The upper set (abbreviated \fIU\fR)
specify the maximal flags that a process can have in its inheritable set.  The
lower set (abbreviated \fIL\fR) specify the minimal amount of flags that a
process must have in its inheritable set.  The inheritable set may be changed
at any time, subject to permissions and the lower and upper sets.
.P
To change the security-flags of a process one must have both permissions
equivalent to those required to send a signal to the process and have the
\fBPRIV_PROC_SECFLAGS\fR privilege.
.P
Currently available features are:

.sp
.ne 2
.na
Address Space Layout Randomisation (\fBASLR\fR)
.ad
.RS 11n
The base addresses of the stack, heap and shared library (including
\fBld.so\fR) mappings are randomised, the bases of mapped regions other than
those using \fBMAP_FIXED\fR are randomised.
.P
Currently, executable base addresses are \fInot\fR randomised, due to which
the mitigation provided by this feature is currently limited.
.P
This flag may also be enabled by the presence of the \fBDT_SUNW_ASLR\fR
dynamic tag in the \fB.dynamic\fR section of the executable file. If this
tag has a value of 1, ASLR will be enabled. If the flag has a value of
\fB0\fR ASLR will be disabled. If the tag is not present, the value of the
ASLR flag will be inherited as normal.
.RE
```

```
.sp
.ne 2
.na
Forbid mappings at NULL (\fBFORBIDNULLMAP\fR)
.ad
.RS 11n
Mappings with an address of 0 are forbidden, and return EINVAL rather than
being honored.
.RE

.sp
.ne 2
.na
Make the userspace stack non-executable (\fBNOEXECSTACK\fR)
.ad
.RS 11n
The stack will be mapped without executable permission, and attempts to
execute it will fault.
.RE

System default security-flags are configured via properties on the
\fBsvc:/system/process-security\fR service, which contains a boolean property
per-flag in the \fBdefault\fR, \fBlower\fR and \fBupper\fR, property groups.
For example, to enable ASLR by default you would execute the following
commands:
.sp
.in +2
.nf
# svccfg -s svc:/system/process-security setprop default/aslr = true
.fi
.in -2
.sp
.P
This can be done by any user with the \fBsolaris.smf.value.process-security\fR
authorization.
.P
Since security-flags are strictly inherited, this will not take effect until
the system or zone is next booted.

   6 .TH SMF_METHOD 5 "June 6, 2016"
   6 .TH SMF_METHOD 5 "May 20, 2009"
   7 .SH NAME
   8 smf_method \- service management framework conventions for methods
   9 .SH DESCRIPTION
  10 .sp
  10 .LP
  11 The class of services managed by \fBsvc.startd\fR(1M) in the service management
  12 framework, \fBsmf\fR(5), consists of applications that fit a simple
  13 \fBfork\fR(2)-\fBexec\fR(2) model. The \fBsvc.startd\fR(1M) master daemon and
  14 other restarters support the \fBfork\fR(2)-\fBexec\fR(2) model, potentially
  15 with additional capabilities. The \fBsvc.startd\fR(1M) daemon and other
  16 restarters require that the methods which activate, manipulate, or examine a
  17 service instance follow the conventions described in this manual page.
  18 .SS "Invocation form"
  20 .sp
  19 .LP
  20 The form of a method invocation is not dictated by convention. In some cases, a
  21 method invocation might consist of the direct invocation of the daemon or other
  22 binary executable that provides the service. For cases in which an executable
  23 script or other mediating executable is used, the convention recommends the
  24 form:
  25 .sp
  26 .in +2
  27 .nf
  28 /path/to/method_executable abbr_method_name
  29 .fi
  30 .in -2

  32 .sp
  33 .LP
  34 The \fIabbr_method_name\fR used for the recommended form is a supported method
  35 such as \fBstart\fR or \fBstop\fR. The set of methods supported by a restarter
  36 is given on the related restarter page. The \fBsvc.startd\fR(1M) daemon
  37 supports \fBstart\fR, \fBstop\fR, and \fBrefresh\fR methods.
  38 .sp
  39 .LP
  40 A restarter might define other kinds of methods beyond those referenced in this
  41 page. The conventions surrounding such extensions are defined by the restarter
  42 and might not be identical to those given here.
  43 .SS "Environment Variables"
  46 .sp
  44 .LP
  45 The restarter provides four environment variables to the method that determine
  46 the context in which the method is invoked.
  47 .sp
  48 .ne 2
  49 .na
  50 \fB\fBSMF_FMRI\fR\fR
  51 .ad
  52 .sp .6
  53 .RS 4n
```

```
  54 The service fault management resource identifier (FMRI) of the instance for
  55 which the method is invoked.
  56 .RE

  58 .sp
  59 .ne 2
  60 .na
  61 \fB\fBSMF_METHOD\fR\fR
  62 .ad
  63 .sp .6
  64 .RS 4n
  65 The full name of the method being invoked, such as \fBstart\fR or \fBstop\fR.
  66 .RE

  68 .sp
  69 .ne 2
  70 .na
  71 \fB\fBSMF_RESTARTER\fR\fR
  72 .ad
  73 .sp .6
  74 .RS 4n
  75 The service FMRI of the restarter that invokes the method
  76 .RE

  78 .sp
  79 .ne 2
  80 .na
  81 \fB\fBSMF_ZONENAME\fR\fR
  82 .ad
  83 .sp .6
  84 .RS 4n
  85 The name of the zone in which the method is running. This can also be obtained
  86 by using the \fBzonename\fR(1) command.
  87 .RE

  89 .sp
  90 .LP
  91 These variables should be removed from the environment prior to the invocation
  92 of any persistent process by the method. A convenience shell function,
  93 \fBsmf_clear_env\fR, is given for service authors who use Bourne-compatible
  94 shell scripting to compose service methods in the include file described below.
  95 .sp
  96 .LP
  97 The method context can cause other environment variables to be set as described
  98 below.
  99 .SS "Method Definition"
 103 .sp
 100 .LP
 101 A method is defined minimally by three properties in a propertygroup of type
 102 \fBmethod\fR.
 103 .sp
 104 .LP
 105 These properties are:
 106 .sp
 107 .ne 2
 108 .na
 109 \fBexec (\fIastring\fR)\fR
 110 .ad
 111 .RS 27n
 112 Method executable string.
 113 .RE

 115 .sp
 116 .ne 2
 117 .na
 118 \fBtimeout_seconds (\fIcount\fR)\fR
```

```
119 .ad
120 .RS 27n
121 Number of seconds before method times out. See the \fBTimeouts\fR section for
122 more detail.
123 .RE

125 .sp
126 .ne 2
127 .na
128 \fBtype (\fIastring\fR)\fR
129 .ad
130 .RS 27n
131 Method type. Currently always set to \fBmethod\fR.
132 .RE

134 .sp
135 .LP
136 A Method Context can be defined to further refine the execution environment of
137 the method. See the \fBMethod Context\fR section for more information.
138 .SS "Method Tokens"
143 .sp
139 .LP
140 When defined in the \fBexec\fR string of the method by the restarter
141 \fBsvc.startd\fR, a set of tokens are parsed and expanded with appropriate
142 value. Other restarters might not support method tokens. The delegated
143 restarter for inet services, \fBinetd\fR(1M), does not support the following
144 method expansions.
145 .sp
146 .ne 2
147 .na
148 \fB\fB%%\fR\fR
149 .ad
150 .sp .6
151 .RS 4n
152 %
153 .RE

155 .sp
156 .ne 2
157 .na
158 \fB\fB%r\fR\fR
159 .ad
160 .sp .6
161 .RS 4n
162 Name of the restarter, such as \fBsvc.startd\fR
163 .RE

165 .sp
166 .ne 2
167 .na
168 \fB\fB%m\fR\fR
169 .ad
170 .sp .6
171 .RS 4n
172 The full name of the method being invoked, such as \fBstart\fR or \fBstop\fR.
173 .RE

175 .sp
176 .ne 2
177 .na
178 \fB\fB%s\fR\fR
179 .ad
180 .sp .6
181 .RS 4n
182 Name of the service
183 .RE
```

```
185 .sp
186 .ne 2
187 .na
188 \fB\fB%i\fR\fR
189 .ad
190 .sp .6
191 .RS 4n
192 Name of the instance
193 .RE

195 .sp
196 .ne 2
197 .na
198 \fB\fB\fR\fB%f\fR\fR
199 .ad
200 .sp .6
201 .RS 4n
202 FMRI of the instance
203 .RE

205 .sp
206 .ne 2
207 .na
208 \fB\fB%{prop[:,]}\fR\fR
209 .ad
210 .sp .6
211 .RS 4n
212 Value(s) of a property. The \fBprop\fR might be a property FMRI, a property
213 group name and a property name separated by a \fB/\fR, or a property name in
214 the \fBapplication\fR property group. These values can be followed by a \fB,\fR
215 (comma) or \fB:\fR (colon). If present, the separators are used to separate
216 multiple values. If absent, a space is used. The following shell metacharacters
217 encountered in string values are quoted with a \ (backslash):
218 .sp
219 .in +2
220 .nf
221 ; & ( ) | ^ < > newline space tab  \  " ’
222 .fi
223 .in -2

225 An invalid expansion constitutes method failure.
226 .RE

228 .sp
229 .LP
230 Two explicit tokens can be used in the place of method commands.
231 .sp
232 .ne 2
233 .na
234 \fB\fB:kill [-signal]\fR\fR
235 .ad
236 .sp .6
237 .RS 4n
238 Sends the specified signal, which is \fBSIGTERM\fR by default, to all processes
239 in the primary instance contract. Always returns \fBSMF_EXIT_OK\fR. This token
240 should be used to replace common \fBpkill\fR invocations.
241 .RE

243 .sp
244 .ne 2
245 .na
246 \fB\fB:true\fR\fR
247 .ad
248 .sp .6
249 .RS 4n
```

```
250 Always returns \fBSMF_EXIT_OK\fR. This token should be used for methods that
251 are required by the restarter but which are unnecessary for the particular
252 service implementation.
253 .RE

255 .SS "Exiting and Exit Status"
261 .sp
256 .LP
257 The required behavior of a start method is to delay exiting until the service
258 instance is ready to answer requests or is otherwise functional.
259 .sp
260 .LP
261 The following exit status codes are defined in \fB<libscf.h>\fR and in the
262 shell support file.
263 .sp

265 .sp
266 .TS
267 l l l
268 l l l .
269 \fBSMF_EXIT_OK\fR       \fB0\fR T{
270 Method exited, performing its operation successfully.
271 T}
272 \fBSMF_EXIT_ERR_FATAL\fR        \fB95\fR        T{
273 Method failed fatally and is unrecoverable without administrative intervention.
274 T}
275 \fBSMF_EXIT_ERR_CONFIG\fR       \fB96\fR        T{
276 Unrecoverable configuration error. A common condition that returns this exit sta
277 T}
278 \fBSMF_EXIT_ERR_NOSMF\fR        \fB99\fR        T{
279 Method has been mistakenly invoked outside the \fBsmf\fR(5) facility. Services t
280 T}
281 \fBSMF_EXIT_ERR_PERM\fR \fB100\fR       T{
282 Method requires a form of permission such as file access, privilege, authorizati
283 T}
284 \fBSMF_EXIT_ERR_OTHER\fR        \fBnon-zero\fR  T{
285 Any non-zero exit status from a method is treated as an unknown error. A series
286 T}
287 .TE

289 .sp
290 .LP
291 Use of a precise exit code allows the responsible restarter to categorize an
292 error response as likely to be intermittent and worth pursuing restart or
293 permanent and request administrative intervention.
294 .SS "Timeouts"
301 .sp
295 .LP
296 Each method can have an independent timeout, given in seconds. The choice of a
297 particular timeout should be based on site expectations for detecting a method
298 failure due to non-responsiveness. Sites with replicated filesystems or other
299 failover resources can elect to lengthen method timeouts from the default.
300 Sites with no remote resources can elect to shorten the timeouts. Method
301 timeout is specified by the \fBtimeout_seconds\fR property.
302 .sp
303 .LP
304 If you specify \fB0 timeout_seconds\fR for a method, it declares to the
305 restarter that there is no timeout for the service. This setting is not
306 preferred, but is available for services that absolutely require it.
307 .sp
308 .LP
309 \fB-1 timeout_seconds\fR is also accepted, but is a deprecated specification.
310 .SS "Shell Programming Support"
318 .sp
311 .LP
312 A set of environment variables that define the above exit status values is
```

```
313 provided with convenience shell functions in the file
314 \fB/lib/svc/share/smf_include.sh\fR. This file is a Bourne shell script
315 suitable for inclusion via the source operator in any Bourne-compatible shell.
316 .sp
317 .LP
318 To assist in the composition of scripts that can serve as SMF methods as well
319 as \fB/etc/init.d\fR scripts, the \fBsmf_present()\fR shell function is
320 provided. If the \fBsmf\fR(5) facility is not available, \fBsmf_present()\fR
321 returns a non-zero exit status.
322 .sp
323 .LP
324 One possible structure for such a script follows:
325 .sp
326 .in +2
327 .nf
328 if smf_present; then
329       # Shell code to run application as managed service
330       ....

332       smf_clear_env
333 else
334       # Shell code to run application as /etc/init.d script
335       ....
336 fi
337 .fi
338 .in -2

340 .sp
341 .LP
342 This example shows the use of both convenience functions that are provided.
343 .SS "Method Context"
352 .sp
344 .LP
345 The service management facility offers a common mechanism set the context in
346 which the \fBfork\fR(2)-\fBexec\fR(2) model services execute.
347 .sp
348 .LP
349 The desired method context should be provided by the service developer. All
350 service instances should run with the lowest level of privileges possible to
351 limit potential security compromises.
352 .sp
353 .LP
354 A method context can contain the following properties:
355 .sp
356 .ne 2
357 .na
358 \fB\fBuse_profile\fR\fR
359 .ad
360 .sp .6
361 .RS 4n
362 A boolean that specifies whether the profile should be used instead of the
363 \fBuser\fR, \fBgroup\fR, \fBprivileges\fR, and \fBlimit_privileges\fR
364 properties.
365 .RE

367 .sp
368 .ne 2
369 .na
370 \fBenvironment\fR
371 .ad
372 .sp .6
373 .RS 4n
374 Environment variables to insert into the environment of the method, in the form
375 of a number of \fBNAME=value\fR strings.
376 .RE
```

```
.sp
.ne 2
.na
\fB\fBprofile\fR\fR
.ad
.sp .6
.RS 4n
The name of an RBAC (role-based access control) profile which, along with the
method executable, identifies an entry in \fBexec_attr\fR(4).
.RE

.sp
.ne 2
.na
\fB\fBuser\fR\fR
.ad
.sp .6
.RS 4n
The user ID in numeric or text form.
.RE

.sp
.ne 2
.na
\fB\fBgroup\fR\fR
.ad
.sp .6
.RS 4n
The group ID in numeric or text form.
.RE

.sp
.ne 2
.na
\fB\fBsupp_groups\fR\fR
.ad
.sp .6
.RS 4n
An optional string that specifies the supplemental group memberships by ID, in
numeric or text form.
.RE

.sp
.ne 2
.na
\fB\fBprivileges\fR\fR
.ad
.sp .6
.RS 4n
An optional string specifying the privilege set as defined in
\fBprivileges\fR(5).
.RE

.sp
.ne 2
.na
\fB\fBlimit_privileges\fR\fR
.ad
.sp .6
.RS 4n
An optional string specifying the limit privilege set as defined in
\fBprivileges\fR(5).
.RE

.sp
.ne 2
```

```
.na
\fB\fBworking_directory\fR\fR
.ad
.sp .6
.RS 4n
The home directory from which to launch the method. \fB:home\fR can be used as
a token to indicate the home directory of the user whose \fBuid\fR is used to
launch the method. If the property is unset, \fB:home\fR is used.
.RE

.sp
.ne 2
.na
\fB\fBsecurity_flags\fR\fR
.ad
.sp .6
.RS 4n
The security flags to apply when launching the method.  See \fBsecurity-flags\fR
.sp
.LP
The "default" keyword specifies those flags specified in
\fBsvc:/system/process-security\fR.  The "all" keyword enables all flags, the
"none" keyword enables no flags.  Further flags may be added by specifying
their name, or removed by specifying their name prefixed by '-' or '!'.
.sp
.LP
Use of "all" has associated risks, as future versions of the system may
include further flags which may harm poorly implemented software.
.RE

.sp
.ne 2
.na
#endif /* ! codereview */
\fB\fBcorefile_pattern\fR\fR
.ad
.sp .6
.RS 4n
An optional string that specifies the corefile pattern to use for the service,
as per \fBcoreadm\fR(1M). Most restarters supply a default. Setting this
property overrides local customizations to the global core pattern.
.RE

.sp
.ne 2
.na
\fB\fBproject\fR\fR
.ad
.sp .6
.RS 4n
The project ID in numeric or text form. \fB:default\fR can be used as a token
to indicate a project identified by \fBgetdefaultproj\fR(3PROJECT) for the user
whose \fBuid\fR is used to launch the method.
.RE

.sp
.ne 2
.na
\fB\fBresource_pool\fR\fR
.ad
.sp .6
.RS 4n
The resource pool name on which to launch the method. \fB:default\fR can be
used as a token to indicate the pool specified in the \fBproject\fR(4) entry
given in the \fBproject\fR attribute above.
.RE
```

```
.sp
.LP
The method context can be set for the entire service instance by specifying a
\fBmethod_context\fR property group for the service or instance. A method might
override the instance method context by providing the method context properties
on the method property group.
.sp
.LP
Invalid method context settings always lead to failure of the method, with the
exception of invalid environment variables that issue warnings.
.sp
.LP
In addition to the context defined above, many \fBfork\fR(2)-\fBexec\fR(2)
model restarters also use the following conventions when invoking executables
as methods:
.sp
.ne 2
.na
\fBArgument array\fR
.ad
.sp .6
.RS 4n
The arguments in \fBargv[]\fR are set consistently with the result \fB/bin/sh
-c\fR of the \fBexec\fR string.
.RE

.sp
.ne 2
.na
\fBFile descriptors\fR
.ad
.sp .6
.RS 4n
File descriptor \fB0\fR is \fB/dev/null\fR. File descriptors \fB1\fR and
\fB2\fR are recommended to be a per-service log file.
.RE

.SH FILES
.sp
.ne 2
.na
\fB\fB/lib/svc/share/smf_include.sh\fR\fR
.ad
.sp .6
.RS 4n
Definitions of exit status values.
.RE

.sp
.ne 2
.na
\fB\fB/usr/include/libscf.h\fR\fR
.ad
.sp .6
.RS 4n
Definitions of exit status codes.
.RE

\fBsecurity-flags\fR(5)
.sp
.LP
The present version of \fBsmf\fR(5) does not support multiple repositories.
.sp
.LP
When a service is configured to be started as root but with privileges
different from \fBlimit_privileges\fR, the resulting process is privilege
aware.  This can be surprising to developers who expect \fBseteuid(<non-zero
UID>)\fR to reduce privileges to basic or less.
```

new/usr/src/pkg/manifests/consolidation-osnet-osnet-message-files.mf
7029 want per-process exploit mitigation features (secflags)
7030 want basic address space layout randomization (aslr)
7031 noexec_user_stack should be a secflag
7032 want a means to forbid mappings around NULL.
