#
# uts/common/Makefile.rules
#
#       This Makefile defines all the file build rules for the directory
# uts/common and its children. These are the source files which may
# be considered common to all SunOS systems.
#
#       The following two-level ordering must be maintained in this file.
#         Lines are sorted first in order of decreasing specificity based on
#         the first directory component.  That is, sun4u rules come before
#         sparc rules come before common rules.
#
#         Lines whose initial directory components are equal are sorted
#         alphabetically by the remaining components.

#
#       Section 1a: C objects build rules
#

 709 /*
 710  * ROUTINE:     AUDIT_CLOSEF
 711  * PURPOSE:
 712  * CALLBY:      CLOSEF
 713  * NOTE:
 714  * release per file audit resources when file structure is being released.
 715  *
 716  * IMPORTANT NOTE: Since we generate an audit record here, we may sleep
 717  *      on the audit queue if it becomes full. This means
 718  *      audit_closef can not be called when f_count == 0. Since
 719  *      f_count == 0 indicates the file structure is free, another
 720  *      process could attempt to use the file while we were still
 721  *      asleep waiting on the audit queue. This would cause the
 722  *      per file audit data to be corrupted when we finally do
 723  *      wakeup.
 724  * TODO:
 725  * QUESTION:
 726  */

new/usr/src/uts/common/c2/audit_kevents.h
7029 want per-process exploit mitigation features (secflags)
7030 want basic address space layout randomization (aslr)
7031 noexec_user_stack should be a secflag
7032 want a means to forbid mappings around NULL.

 * Generic chained copyout buffers for procfs use.
 * In order to prevent procfs from making huge oversize kmem_alloc calls,
 * a list of smaller buffers can be concatenated and copied to userspace in
 * sequence.
 *
 * The implementation is opaque.
 *
 * A user of this will perform the following steps:
 *
 *      list_t  listhead;
 *      struct my *mp;
 *
 *      pr_iol_initlist(&listhead, sizeof (*mp), n);
 *      while (whatever) {
 *              mp = pr_iol_newbuf(&listhead, sizeof (*mp);
 *              ...
 *              error = ...
 *      }
 *
 * When done, depending on whether copyout() or uiomove() is supposed to
 * be used for transferring the buffered data to userspace, call either:
 *
 *      error = pr_iol_copyout_and_free(&listhead, &cmaddr, error);
 *
 * or else:
 *
 *      error = pr_iol_uiomove_and_free(&listhead, uiop, error);
 *
 * These two functions will in any case kmem_free() all list items, but
 * if an error occurred before they will not perform the copyout/uiomove.
 * If copyout/uiomove are done, the passed target address / uio_t
 * are updated. The error returned will either be the one passed in, or
 * the error that occurred during copyout/uiomove.

  55 /*
  56  * Theory statement:
  57  *
  58  * The main driving force behind mmapobj is to interpret and map ELF files
```

```
  59  * inside of the kernel instead of having the linker be responsible for this.
  60  *
  61  * mmapobj also supports the AOUT 4.x binary format as well as flat files in
  62  * a read only manner.
  63  *
  64  * When interpreting and mapping an ELF file, mmapobj will map each PT_LOAD
  65  * or PT_SUNWBSS segment according to the ELF standard.  Refer to the "Linker
  66  * and Libraries Guide" for more information about the standard and mapping
  67  * rules.
  68  *
  69  * Having mmapobj interpret and map objects will allow the kernel to make the
  70  * best decision for where to place the mappings for said objects.  Thus, we
  71  * can make optimizations inside of the kernel for specific platforms or cache
  72  * mapping information to make mapping objects faster.  The cache is ignored
  73  * if ASLR is enabled.
  71  * can make optimizations inside of the kernel for specific platforms or
  72  * cache mapping information to make mapping objects faster.
  74  *
  75  * The lib_va_hash will be one such optimization.  For each ELF object that
  76  * mmapobj is asked to interpret, we will attempt to cache the information
  77  * about the PT_LOAD and PT_SUNWBSS sections to speed up future mappings of
  78  * the same objects.  We will cache up to LIBVA_CACHED_SEGS (see below) program
  79  * headers which should cover a majority of the libraries out there without
  80  * wasting space.  In order to make sure that the cached information is valid,
  81  * we check the passed in vnode's mtime and ctime to make sure the vnode
  82  * has not been modified since the last time we used it.
  83  *
  84  * In addition, the lib_va_hash may contain a preferred starting VA for the
  85  * object which can be useful for platforms which support a shared context.
  86  * This will increase the likelyhood that library text can be shared among
  87  * many different processes.  We limit the reserved VA space for 32 bit objects
  88  * in order to minimize fragmenting the processes address space.
  89  *
  90  * In addition to the above, the mmapobj interface allows for padding to be
  91  * requested before the first mapping and after the last mapping created.
  92  * When padding is requested, no additional optimizations will be made for
  93  * that request.
  94  */

  96 /*
  97  * Threshold to prevent allocating too much kernel memory to read in the
  98  * program headers for an object.  If it requires more than below,
  99  * we will use a KM_NOSLEEP allocation to allocate memory to hold all of the
 100  * program headers which could possibly fail.  If less memory than below is
 101  * needed, then we use a KM_SLEEP allocation and are willing to wait for the
 102  * memory if we need to.

  59 /*
  60  * There are two possible layers of privilege routines and two possible
  61  * levels of secpolicy.  Plus one other we may not be interested in, so
  62  * we may need as many as 6 but no more.
  63  */
  64 #define MAXPRIVSTACK            6

  66 int priv_debug = 0;
  67 int priv_basic_test = -1;

  69 /*
  70  * This file contains the majority of the policy routines.
  71  * Since the policy routines are defined by function and not
  72  * by privilege, there is quite a bit of duplication of
  73  * functions.
  74  *
  75  * The secpolicy functions must not make assumptions about
  76  * locks held or not held as any lock can be held while they're
  77  * being called.
  78  *
  79  * Credentials are read-only so no special precautions need to
  80  * be taken while locking them.
  81  *
  82  * When a new policy check needs to be added to the system the
  83  * following procedure should be followed:
  84  *
  85  *              Pick an appropriate secpolicy_*() function
  86  *                      -> done if one exists.
  87  *              Create a new secpolicy function, preferably with
  88  *              a descriptive name using the standard template.
  89  *              Pick an appropriate privilege for the policy.
  90  *              If no appropraite privilege exists, define new one
  91  *              (this should be done with extreme care; in most cases
  92  *              little is gained by adding another privilege)
  93  *
  94  * WHY ROOT IS STILL SPECIAL.
  95  *
  96  * In a number of the policy functions, there are still explicit
  97  * checks for uid 0.  The rationale behind these is that many root
  98  * owned files/objects hold configuration information which can give full
  99  * privileges to the user once written to.  To prevent escalation
 100  * of privilege by allowing just a single privilege to modify root owned
 101  * objects, we've added these root specific checks where we considered
 102  * them necessary: modifying root owned files, changing uids to 0, etc.
 103  *
 104  * PRIVILEGE ESCALATION AND ZONES.
 105  *
 106  * A number of operations potentially allow the caller to achieve
 107  * privileges beyond the ones normally required to perform the operation.
 108  * For example, if allowed to create a setuid 0 executable, a process can
 109  * gain privileges beyond PRIV_FILE_SETID.  Zones, however, place
 110  * restrictions on the ability to gain privileges beyond those available
 111  * within the zone through file and process manipulation.  Hence, such
 112  * operations require that the caller have an effective set that includes
 113  * all privileges available within the current zone, or all privileges
 114  * if executing in the global zone.
 115  *
 116  * This is indicated in the priv_policy* policy checking functions
 117  * through a combination of parameters.  The "priv" parameter indicates
 118  * the privilege that is required, and the "allzone" parameter indicates
 119  * whether or not all privileges in the zone are required.  In addition,
 120  * priv can be set to PRIV_ALL to indicate that all privileges are
 121  * required (regardless of zone).  There are three scenarios of interest:
 122  * (1) operation requires a specific privilege
 123  * (2) operation requires a specific privilege, and requires all
 124  *     privileges available within the zone (or all privileges if in
```

```
125  *     the global zone)
126  * (3) operation requires all privileges, regardless of zone
127  *
128  * For (1), priv should be set to the specific privilege, and allzone
129  * should be set to B_FALSE.
130  * For (2), priv should be set to the specific privilege, and allzone
131  * should be set to B_TRUE.
132  * For (3), priv should be set to PRIV_ALL, and allzone should be set
133  * to B_FALSE.
134  *
135  */

  25 INSERT COMMENT
  26  */

  28 #
  29 # Privileges can be added to this file at any location, not
  30 # necessarily at the end.  For patches, it is probably best to
  31 # add the new privilege at the end; for ordinary releases privileges
  32 # should be ordered alphabetically.
  33 #

  35 privilege PRIV_CONTRACT_EVENT

  37         Allows a process to request critical events without limitation.
  38         Allows a process to request reliable delivery of all events on
  39         any event queue.

  41 privilege PRIV_CONTRACT_IDENTITY

  43         Allows a process to set the service FMRI value of a process
  44         contract template.

  46 privilege PRIV_CONTRACT_OBSERVER

  48         Allows a process to observe contract events generated by
  49         contracts created and owned by users other than the process's
  50         effective user ID.
  51         Allows a process to open contract event endpoints belonging to
  52         contracts created and owned by users other than the process's
  53         effective user ID.

  55 privilege PRIV_CPC_CPU

  57         Allow a process to access per-CPU hardware performance counters.
```

```
  59 privilege PRIV_DTRACE_KERNEL

  61         Allows DTrace kernel-level tracing.

  63 privilege PRIV_DTRACE_PROC

  65         Allows DTrace process-level tracing.
  66         Allows process-level tracing probes to be placed and enabled in
  67         processes to which the user has permissions.

  69 privilege PRIV_DTRACE_USER

  71         Allows DTrace user-level tracing.
  72         Allows use of the syscall and profile DTrace providers to
  73         examine processes to which the user has permissions.

  75 privilege PRIV_FILE_CHOWN

  77         Allows a process to change a file's owner user ID.
  78         Allows a process to change a file's group ID to one other than
  79         the process' effective group ID or one of the process'
  80         supplemental group IDs.

  82 privilege PRIV_FILE_CHOWN_SELF

  84         Allows a process to give away its files; a process with this
  85         privilege will run as if {_POSIX_CHOWN_RESTRICTED} is not
  86         in effect.

  88 privilege PRIV_FILE_DAC_EXECUTE

  90         Allows a process to execute an executable file whose permission
  91         bits or ACL do not allow the process execute permission.

  93 privilege PRIV_FILE_DAC_READ

  95         Allows a process to read a file or directory whose permission
  96         bits or ACL do not allow the process read permission.

  98 privilege PRIV_FILE_DAC_SEARCH

 100         Allows a process to search a directory whose permission bits or
 101         ACL do not allow the process search permission.

 103 privilege PRIV_FILE_DAC_WRITE

 105         Allows a process to write a file or directory whose permission
 106         bits or ACL do not allow the process write permission.
 107         In order to write files owned by uid 0 in the absence of an
 108         effective uid of 0 ALL privileges are required.

 110 privilege PRIV_FILE_DOWNGRADE_SL

 112         Allows a process to set the sensitivity label of a file or
 113         directory to a sensitivity label that does not dominate the
 114         existing sensitivity label.
 115         This privilege is interpreted only if the system is configured
 116         with Trusted Extensions.

 118 privilege PRIV_FILE_FLAG_SET

 120         Allows a process to set immutable, nounlink or appendonly
 121         file attributes.

 123 basic privilege PRIV_FILE_LINK_ANY
```

```
125         Allows a process to create hardlinks to files owned by a uid
126         different from the process' effective uid.

128 privilege PRIV_FILE_OWNER

130         Allows a process which is not the owner of a file or directory
131         to perform the following operations that are normally permitted
132         only for the file owner: modify that file's access and
133         modification times; remove or rename a file or directory whose
134         parent directory has the ''save text image after execution''
135         (sticky) bit set; mount a ''namefs'' upon a file; modify
136         permission bits or ACL except for the set-uid and set-gid
137         bits.

139 basic privilege PRIV_FILE_READ

141         Allows a process to read objects in the filesystem.

143 privilege PRIV_FILE_SETID

145         Allows a process to change the ownership of a file or write to
146         a file without the set-user-ID and set-group-ID bits being
147         cleared.
148         Allows a process to set the set-group-ID bit on a file or
149         directory whose group is not the process' effective group or
150         one of the process' supplemental groups.
151         Allows a process to set the set-user-ID bit on a file with
152         different ownership in the presence of PRIV_FILE_OWNER.
153         Additional restrictions apply when creating or modifying a
154         set-uid 0 file.

156 privilege PRIV_FILE_UPGRADE_SL

158         Allows a process to set the sensitivity label of a file or
159         directory to a sensitivity label that dominates the existing
160         sensitivity label.
161         This privilege is interpreted only if the system is configured
162         with Trusted Extensions.

164 basic privilege PRIV_FILE_WRITE

166         Allows a process to modify objects in the filesystem.

168 privilege PRIV_GRAPHICS_ACCESS

170         Allows a process to make privileged ioctls to graphics devices.
171         Typically only xserver process needs to have this privilege.
172         A process with this privilege is also allowed to perform
173         privileged graphics device mappings.

175 privilege PRIV_GRAPHICS_MAP

177         Allows a process to perform privileged mappings through a
178         graphics device.

180 privilege PRIV_IPC_DAC_READ

182         Allows a process to read a System V IPC
183         Message Queue, Semaphore Set, or Shared Memory Segment whose
184         permission bits do not allow the process read permission.
185         Allows a process to read remote shared memory whose
186         permission bits do not allow the process read permission.

188 privilege PRIV_IPC_DAC_WRITE

190         Allows a process to write a System V IPC
```

```
191         Message Queue, Semaphore Set, or Shared Memory Segment whose
192         permission bits do not allow the process write permission.
193         Allows a process to read remote shared memory whose
194         permission bits do not allow the process write permission.
195         Additional restrictions apply if the owner of the object has uid 0
196         and the effective uid of the current process is not 0.

198 privilege PRIV_IPC_OWNER

200         Allows a process which is not the owner of a System
201         V IPC Message Queue, Semaphore Set, or Shared Memory Segment to
202         remove, change ownership of, or change permission bits of the
203         Message Queue, Semaphore Set, or Shared Memory Segment.
204         Additional restrictions apply if the owner of the object has uid 0
205         and the effective uid of the current process is not 0.

207 basic privilege PRIV_NET_ACCESS

209         Allows a process to open a TCP, UDP, SDP or SCTP network endpoint.

211 privilege PRIV_NET_BINDMLP

213         Allow a process to bind to a port that is configured as a
214         multi-level port(MLP) for the process's zone. This privilege
215         applies to both shared address and zone-specific address MLPs.
216         See tnzonecfg(4) from the Trusted Extensions manual pages for
217         information on configuring MLP ports.
218         This privilege is interpreted only if the system is configured
219         with Trusted Extensions.

221 privilege PRIV_NET_ICMPACCESS

223         Allows a process to send and receive ICMP packets.

225 privilege PRIV_NET_MAC_AWARE

227         Allows a process to set NET_MAC_AWARE process flag by using
228         setpflags(2). This privilege also allows a process to set
229         SO_MAC_EXEMPT socket option by using setsockopt(3SOCKET).
230         The NET_MAC_AWARE process flag and the SO_MAC_EXEMPT socket
231         option both allow a local process to communicate with an
232         unlabeled peer if the local process' label dominates the
233         peer's default label, or if the local process runs in the
234         global zone.
235         This privilege is interpreted only if the system is configured
236         with Trusted Extensions.

238 privilege PRIV_NET_MAC_IMPLICIT

240         Allows a process to set SO_MAC_IMPLICIT option by using
241         setsockopt(3SOCKET).  This allows a privileged process to
242         transmit implicitly-labeled packets to a peer.
243         This privilege is interpreted only if the system is configured
244         with Trusted Extensions.

246 privilege PRIV_NET_OBSERVABILITY

248         Allows a process to access /dev/lo0 and the devices in /dev/ipnet/
249         while not requiring them to need PRIV_NET_RAWACCESS.

251 privilege PRIV_NET_PRIVADDR

253         Allows a process to bind to a privileged port
254         number. The privilege port numbers are 1-1023 (the traditional
255         UNIX privileged ports) as well as those ports marked as
256         "udp/tcp_extra_priv_ports" with the exception of the ports
```

```
257         reserved for use by NFS.

259 privilege PRIV_NET_RAWACCESS

261         Allows a process to have direct access to the network layer.

263 unsafe privilege PRIV_PROC_AUDIT

265         Allows a process to generate audit records.
266         Allows a process to get its own audit pre-selection information.

268 privilege PRIV_PROC_CHROOT

270         Allows a process to change its root directory.

272 privilege PRIV_PROC_CLOCK_HIGHRES

274         Allows a process to use high resolution timers.

276 basic privilege PRIV_PROC_EXEC

278         Allows a process to call execve().

280 basic privilege PRIV_PROC_FORK

282         Allows a process to call fork1()/forkall()/vfork()

284 basic privilege PRIV_PROC_INFO

286         Allows a process to examine the status of processes other
287         than those it can send signals to.  Processes which cannot
288         be examined cannot be seen in /proc and appear not to exist.

290 privilege PRIV_PROC_LOCK_MEMORY

292         Allows a process to lock pages in physical memory.

294 privilege PRIV_PROC_MEMINFO

296         Allows a process to access physical memory information.

298 privilege PRIV_PROC_OWNER

300         Allows a process to send signals to other processes, inspect
301         and modify process state to other processes regardless of
302         ownership.  When modifying another process, additional
303         restrictions apply:  the effective privilege set of the
304         attaching process must be a superset of the target process'
305         effective, permitted and inheritable sets; the limit set must
306         be a superset of the target's limit set; if the target process
307         has any uid set to 0 all privilege must be asserted unless the
308         effective uid is 0.
309         Allows a process to bind arbitrary processes to CPUs.

311 privilege PRIV_PROC_PRIOUP

313         Allows a process to elevate its priority above its current level.

315 privilege PRIV_PROC_PRIOCNTL

317         Allows all that PRIV_PROC_PRIOUP allows.
318         Allows a process to change its scheduling class to any scheduling class,
319         including the RT class.

321 basic privilege PRIV_PROC_SECFLAGS
```

```
323         Allows a process to manipulate the secflags of processes (subject to,
324         additionally, the ability to signal that process)

326 #endif /* ! codereview */
327 basic privilege PRIV_PROC_SESSION

329         Allows a process to send signals or trace processes outside its
330         session.

332 unsafe privilege PRIV_PROC_SETID

334         Allows a process to set its uids at will.
335         Assuming uid 0 requires all privileges to be asserted.

337 privilege PRIV_PROC_TASKID

339         Allows a process to assign a new task ID to the calling process.

341 privilege PRIV_PROC_ZONE

343         Allows a process to trace or send signals to processes in
344         other zones.

346 privilege PRIV_SYS_ACCT

348         Allows a process to enable and disable and manage accounting through
349         acct(2), getacct(2), putacct(2) and wracct(2).

351 privilege PRIV_SYS_ADMIN

353         Allows a process to perform system administration tasks such
354         as setting node and domain name and specifying nscd and coreadm
355         settings.

357 privilege PRIV_SYS_AUDIT

359         Allows a process to start the (kernel) audit daemon.
360         Allows a process to view and set audit state (audit user ID,
361         audit terminal ID, audit sessions ID, audit pre-selection mask).
362         Allows a process to turn off and on auditing.
363         Allows a process to configure the audit parameters (cache and
364         queue sizes, event to class mappings, policy options).

366 privilege PRIV_SYS_CONFIG

368         Allows a process to perform various system configuration tasks.
369         Allows a process to add and remove swap devices; when adding a swap
370         device, a process must also have sufficient privileges to read from
371         and write to the swap device.

373 privilege PRIV_SYS_DEVICES

375         Allows a process to successfully call a kernel module that
376         calls the kernel drv_priv(9F) function to check for allowed
377         access.
378         Allows a process to open the real console device directly.
379         Allows a process to open devices that have been exclusively opened.

381 privilege PRIV_SYS_IPC_CONFIG

383         Allows a process to increase the size of a System V IPC Message
384         Queue buffer.

386 privilege PRIV_SYS_LINKDIR

388         Allows a process to unlink and link directories.
```

```
390 privilege PRIV_SYS_MOUNT

392         Allows filesystem specific administrative procedures, such as
393         filesystem configuration ioctls, quota calls and creation/deletion
394         of snapshots.
395         Allows a process to mount and unmount filesystems which would
396         otherwise be restricted (i.e., most filesystems except
397         namefs).
398         A process performing a mount operation needs to have
399         appropriate access to the device being mounted (read-write for
400         "rw" mounts, read for "ro" mounts).
401         A process performing any of the aforementioned
402         filesystem operations needs to have read/write/owner
403         access to the mount point.
404         Only regular files and directories can serve as mount points
405         for processes which do not have all zone privileges asserted.
406         Unless a process has all zone privileges, the mount(2)
407         system call will force the "nosuid" and "restrict" options, the
408         latter only for autofs mountpoints.
409         Regardless of privileges, a process running in a non-global zone may
410         only control mounts performed from within said zone.
411         Outside the global zone, the "nodevices" option is always forced.

413 privilege PRIV_SYS_IPTUN_CONFIG

415         Allows a process to configure IP tunnel links.

417 privilege PRIV_SYS_DL_CONFIG

419         Allows a process to configure all classes of datalinks, including
420         configuration allowed by PRIV_SYS_IPTUN_CONFIG.

422 privilege PRIV_SYS_IP_CONFIG

424         Allows a process to configure a system's IP interfaces and routes.
425         Allows a process to configure network parameters using ndd.
426         Allows a process access to otherwise restricted information using ndd.
427         Allows a process to configure IPsec.
428         Allows a process to pop anchored STREAMs modules with matching zoneid.

430 privilege PRIV_SYS_NET_CONFIG

432         Allows all that PRIV_SYS_IP_CONFIG, PRIV_SYS_DL_CONFIG, and
433         PRIV_SYS_PPP_CONFIG allow.
434         Allows a process to push the rpcmod STREAMs module.
435         Allows a process to INSERT/REMOVE STREAMs modules on locations other
436         than the top of the module stack.

438 privilege PRIV_SYS_NFS

440         Allows a process to perform Sun private NFS specific system calls.
441         Allows a process to bind to ports reserved by NFS: ports 2049 (nfs)
442         and port 4045 (lockd).

444 privilege PRIV_SYS_PPP_CONFIG

446         Allows a process to create and destroy PPP (sppp) interfaces.
447         Allows a process to configure PPP tunnels (sppptun).

449 privilege PRIV_SYS_RES_BIND

451         Allows a process to bind processes to processor sets.

453 privilege PRIV_SYS_RES_CONFIG
```

```
455         Allows all that PRIV_SYS_RES_BIND allows.
456         Allows a process to create and delete processor sets, assign
457         CPUs to processor sets and override the PSET_NOESCAPE property.
458         Allows a process to change the operational status of CPUs in
459         the system using p_online(2).
460         Allows a process to configure resource pools and to bind
461         processes to pools

463 unsafe privilege PRIV_SYS_RESOURCE

465         Allows a process to modify the resource limits specified
466         by setrlimit(2) and setrctl(2) without restriction.
467         Allows a process to exceed the per-user maximum number of
468         processes.
469         Allows a process to extend or create files on a filesystem that
470         has less than minfree space in reserve.

472 privilege PRIV_SYS_SMB

474         Allows a process to access the Sun private SMB kernel module.
475         Allows a process to bind to ports reserved by NetBIOS and SMB:
476         ports 137 (NBNS), 138 (NetBIOS Datagram Service), 139 (NetBIOS
477         Session Service and SMB-over-NBT) and 445 (SMB-over-TCP).

479 privilege PRIV_SYS_SUSER_COMPAT

481         Allows a process to successfully call a third party loadable module
482         that calls the kernel suser() function to check for allowed access.
483         This privilege exists only for third party loadable module
484         compatibility and is not used by Solaris proper.

486 privilege PRIV_SYS_TIME

488         Allows a process to manipulate system time using any of the
489         appropriate system calls: stime, adjtime, ntp_adjtime and
490         the IA specific RTC calls.

492 privilege PRIV_SYS_TRANS_LABEL

494         Allows a process to translate labels that are not dominated
495         by the process' sensitivity label to and from an external
496         string form.
497         This privilege is interpreted only if the system is configured
498         with Trusted Extensions.

500 privilege PRIV_VIRT_MANAGE

502         Allows a process to manage virtualized environments such as
503         xVM(5).

505 privilege PRIV_WIN_COLORMAP

507         Allows a process to override colormap restrictions.
508         Allows a process to install or remove colormaps.
509         Allows a process to retrieve colormap cell entries allocated
510         by other processes.
511         This privilege is interpreted only if the system is configured
512         with Trusted Extensions.

514 privilege PRIV_WIN_CONFIG

516         Allows a process to configure or destroy resources that are
517         permanently retained by the X server.
518         Allows a process to use SetScreenSaver to set the screen
519         saver timeout value.
520         Allows a process to use ChangeHosts to modify the display
```

```
521         access control list.
522         Allows a process to use GrabServer.
523         Allows a process to use the SetCloseDownMode request which
524         may retain window, pixmap, colormap, property, cursor, font,
525         or graphic context resources.
526         This privilege is interpreted only if the system is configured
527         with Trusted Extensions.

529 privilege PRIV_WIN_DAC_READ

531         Allows a process to read from a window resource that it does
532         not own (has a different user ID).
533         This privilege is interpreted only if the system is configured
534         with Trusted Extensions.

536 privilege PRIV_WIN_DAC_WRITE

538         Allows a process to write to or create a window resource that
539         it does not own (has a different user ID). A newly created
540         window property is created with the window's user ID.
541         This privilege is interpreted only if the system is configured
542         with Trusted Extensions.

544 privilege PRIV_WIN_DEVICES

546         Allows a process to perform operations on window input devices.
547         Allows a process to get and set keyboard and pointer controls.
548         Allows a process to modify pointer button and key mappings.
549         This privilege is interpreted only if the system is configured
550         with Trusted Extensions.

552 privilege PRIV_WIN_DGA

554         Allows a process to use the direct graphics access (DGA) X protocol
555         extensions. Direct process access to the frame buffer is still
556         required. Thus the process must have MAC and DAC privileges that
557         allow access to the frame buffer, or the frame buffer must be
558         allocated to the process.
559         This privilege is interpreted only if the system is configured
560         with Trusted Extensions.

562 privilege PRIV_WIN_DOWNGRADE_SL

564         Allows a process to set the sensitivity label of a window resource
565         to a sensitivity label that does not dominate the existing
566         sensitivity label.
567         This privilege is interpreted only if the system is configured
568         with Trusted Extensions.

570 privilege PRIV_WIN_FONTPATH

572         Allows a process to set a font path.
573         This privilege is interpreted only if the system is configured
574         with Trusted Extensions.

576 privilege PRIV_WIN_MAC_READ

578         Allows a process to read from a window resource whose sensitivity
579         label is not equal to the process sensitivity label.
580         This privilege is interpreted only if the system is configured
581         with Trusted Extensions.

583 privilege PRIV_WIN_MAC_WRITE

585         Allows a process to create a window resource whose sensitivity
586         label is not equal to the process sensitivity label.
```

```
587         A newly created window property is created with the window's
588         sensitivity label.
589         This privilege is interpreted only if the system is configured
590         with Trusted Extensions.

592 privilege PRIV_WIN_SELECTION

594         Allows a process to request inter-window data moves without the
595         intervention of the selection confirmer.
596         This privilege is interpreted only if the system is configured
597         with Trusted Extensions.

599 privilege PRIV_WIN_UPGRADE_SL

601         Allows a process to set the sensitivity label of a window
602         resource to a sensitivity label that dominates the existing
603         sensitivity label.
604         This privilege is interpreted only if the system is configured
605         with Trusted Extensions.

607 privilege PRIV_XVM_CONTROL

609         Allows a process access to the xVM(5) control devices for
610         managing guest domains and the hypervisor. This privilege is
611         used only if booted into xVM on x86 platforms.

613 set PRIV_EFFECTIVE

615         Set of privileges currently in effect.

617 set PRIV_INHERITABLE

619         Set of privileges that comes into effect on exec.

621 set PRIV_PERMITTED

623         Set of privileges that can be put into the effective set without
624         restriction.

626 set PRIV_LIMIT

628         Set of privileges that determines the absolute upper bound of
629         privileges this process and its off-spring can obtain.
```

#
# This file generates three different C files:
#
#       <sys/priv_const.h>
#               An implementation private set of manifest integer constant
#               for privileges and privilege sets and manifest constants for
#               set size, number of sets, number of privileges
#
#       os/priv_const.c
#               A C source file containing the set names, privilege names
#               arrays for the name <-> number mappings
#
#       <sys/priv_names.h>
#               A public header file containing the PRIV_* defines
#               that map to strings; these are for convenience.
#               (it's easy to misspell a string, harder to misspell a
#               manifest constant)
#
#       /etc/security/priv_names
#               A privilege name to explanation mapping.
#
#
# The files are output on the awk variable privhfile, pubhfile, cfile,
# and pnamesfile respectively
#
# The input file should contain a standard Sun comment and ident string
# which is copied verbatim and lines of
#
#       [keyword] privilege     PRIV_<privilege>
#       set                     PRIV_<set>
#
# Which are converted to privileges and privilege sets
```

```
#

338  * Sysent initialization macros.
339  *      These take the name string of the system call even though that isn't
340  *      currently used in the sysent entry.  This might be useful someday.
341  *
342  * Initialization macro for system calls which take their args in the C style.
343  * These system calls return the longlong_t return value and must call
344  * set_errno() to return an error.  For SPARC, narg must be at most six.
345  * For more args, use the SYSENT_AP() routine.
346  *
347  * We are able to return two distinct values to userland via the rval_t.
348  * At this time, that corresponds to one 64-bit quantity, or two 32-bit
349  * quantities.  The kernel does not currently need to return two 64-bit
350  * values, or one 128 bit value(!), but we may do one day, so the calling
351  * sequence between userland and the kernel should permit it.
352  *
353  * The interpretation of rval_t is provided by the sy_flags field
354  * which is used to determine how to arrange the results in registers
355  * (or on the stack) for return userland.

2700 /*
2701  * Zones have two reference counts: one for references from credential
2702  * structures (zone_cred_ref), and one (zone_ref) for everything else.
2703  * This is so we can allow a zone to be rebooted while there are still
2704  * outstanding cred references, since certain drivers cache dblks (which
2705  * implicitly results in cached creds).  We wait for zone_ref to drop to
2706  * 0 (actually 1), but not zone_cred_ref.  The zone structure itself is
2707  * later freed when the zone_cred_ref drops to 0, though nothing other
2708  * than the zone id and privilege set should be accessed once the zone
2709  * is "dead".
2710  *
2711  * A debugging flag, zone_wait_for_cred, can be set to a non-zero value
2712  * to force halt/reboot to block waiting for the zone_cred_ref to drop
2713  * to 0.  This can be useful to flush out other sources of cached creds
2714  * that may be less innocuous than the driver case.
2715  *
2716  * Zones also provide a tracked reference counting mechanism in which zone
2717  * references are represented by "crumbs" (zone_ref structures).  Crumbs help
2718  * debuggers determine the sources of leaked zone references.  See
2719  * zone_hold_ref() and zone_rele_ref() below for more information.

7088  * Public interface for looking up a zone by zoneid. It's a customized version
7089  * for netstack_zone_create(). It can only be called from the zsd create
7090  * callbacks, since it doesn't have reference on the zone structure hence if
7091  * it is called elsewhere the zone could disappear after the zonehash_lock
7092  * is dropped.
7093  *
7094  * Furthermore it
7095  * 1. Doesn't check the status of the zone.
7096  * 2. It will be called even before zone_init is called, in that case the
7097  *    address of zone0 is returned directly, and netstack_zone_create()
7098  *    will only assign a value to zone0.zone_netstack, won't break anything.
7099  * 3. Returns without the zone being held.

312  * Version structures.  There are three types of version structure:
313  *
314  *  o   A definition of the versions within the image itself.
315  *      Each version definition is assigned a unique index (starting from
316  *      VER_NDX_BGNDEF) which is used to cross-reference symbols associated to
317  *      the version.  Each version can have one or more dependencies on other
318  *      version definitions within the image.  The version name, and any
319  *      dependency names, are specified in the version definition auxiliary
320  *      array.  Version definition entries require a version symbol index table.
321  *
322  *  o   A version requirement on a needed dependency.  Each needed entry
323  *      specifies the shared object dependency (as specified in DT_NEEDED).
```

```
 *      One or more versions required from this dependency are specified in the
 *      version needed auxiliary array.
 *
 *  o   A version symbol index table.  Each symbol indexes into this array
 *      to determine its version index.  Index values of VER_NDX_BGNDEF or
 *      greater indicate the version definition to which a symbol is associated.
 *      (the size of a symbol index entry is recorded in the sh_info field).

new/usr/src/uts/common/sys/procfs.h
Code review comments from jeffpc
7029 want per-process exploit mitigation features (secflags)
7030 want basic address space layout randomization (aslr)
7031 noexec_user_stack should be a secflag
7032 want a means to forbid mappings around NULL.

134  * Exit values that may be returned by scripts or programs invoked by various
135  * zone commands.
136  *
137  * These are defined as:
138  *
139  *      ZONE_SUBPROC_OK
140  *      ===============
141  *      The subprocess completed successfully.
142  *
143  *      ZONE_SUBPROC_USAGE
144  *      ==================
145  *      The subprocess failed with a usage message, or a usage message should
146  *      be output in its behalf.
147  *
148  *      ZONE_SUBPROC_NOTCOMPLETE
149  *      ========================
150  *      The subprocess did not complete, but the actions performed by the
151  *      subprocess require no recovery actions by the user.
152  *
153  *      For example, if the subprocess were called by "zoneadm install," the
154  *      installation of the zone did not succeed but the user need not perform
155  *      a "zoneadm uninstall" before attempting another install.
156  *
157  *      ZONE_SUBPROC_FATAL
158  *      ==================
159  *      The subprocess failed in a fatal manner, usually one that will require
160  *      some type of recovery action by the user.
161  *
162  *      For example, if the subprocess were called by "zoneadm install," the
163  *      installation of the zone did not succeed and the user will need to
164  *      perform a "zoneadm uninstall" before another install attempt is
165  *      possible.
166  *
167  *      The non-success exit values are large to avoid accidental collision
168  *      with values used internally by some commands (e.g. "Z_ERR" and
169  *      "Z_USAGE" as used by zoneadm.)

741 /*
742  * Anchored in the table below are counters used to keep track
743  * of free contiguous physical memory. Each element of the table contains
744  * the array of counters, the size of array which is allocated during
745  * startup based on physmax and a shift value used to convert a pagenum
746  * into a counter array index or vice versa. The table has page size
747  * for rows and region size for columns:
748  *
749  *      page_counters[page_size][region_size]
750  *
751  *      page_size:      TTE size code of pages on page_size freelist.
752  *
753  *      region_size:    TTE size code of a candidate larger page made up
754  *                      made up of contiguous free page_size pages.
755  *
756  * As you go across a page_size row increasing region_size each
757  * element keeps track of how many (region_size - 1) size groups
758  * made up of page_size free pages can be coalesced into a
759  * regsion_size page. Yuck! Lets try an example:
760  *
761  *      page_counters[1][3] is the table element used for identifying
762  *      candidate 4M pages from contiguous pages off the 64K free list.
763  *      Each index in the page_counters[1][3].array spans 4M. Its the
764  *      number of free 512K size (regsion_size - 1) groups of contiguous
765  *      64K free pages. So when page_counters[1][3].counters[n] == 8
766  *      we know we have a candidate 4M page made up of 512K size groups
767  *      of 64K free pages.
768  */

150  * map_addr_proc() is the routine called when the system is to
151  * choose an address for the user.  We will pick an address
152  * range which is just below the current stack limit.  The
153  * algorithm used for cache consistency on machines with virtual
154  * address caches is such that offset 0 in the vnode is always
155  * on a shm_alignment'ed aligned address.  Unfortunately, this
156  * means that vnodes which are demand paged will not be mapped
157  * cache consistently with the executable images.  When the
158  * cache alignment for a given object is inconsistent, the
159  * lower level code must manage the translations so that this
160  * is not seen here (at the cost of efficiency, of course).
161  *
162  * Every mapping will have a redzone of a single page on either side of
163  * the request. This is done to leave one page unmapped between segments.
164  * This is not required, but it's useful for the user because if their
165  * program strays across a segment boundary, it will catch a fault
166  * immediately making debugging a little easier.  Currently the redzone
167  * is mandatory.
168  *
169  *
170  * addrp is a value/result parameter.
171  *      On input it is a hint from the user to be used in a completely
172  *      machine dependent fashion.  For MAP_ALIGN, addrp contains the
173  *      minimal alignment, which must be some "power of two" multiple of
174  *      pagesize.
175  *
176  *      On output it is NULL if no address can be found in the current
177  *      processes address space or else an address that is currently
178  *      not mapped for len bytes with a page of red zone on either side.
179  *      If vacalign is true, then the selected address will obey the alignment
180  *      constraints of a vac machine based on the given off value.

 * Contiguous memory allocator data structures and variables.
 *
 * The sun4v kernel must provide a means to allocate physically
 * contiguous, non-relocatable memory. The contig_mem_arena
 * and contig_mem_slab_arena exist for this purpose. Allocations
 * that require physically contiguous non-relocatable memory should
 * be made using contig_mem_alloc() or contig_mem_alloc_align()
 * which return memory from contig_mem_arena or contig_mem_reloc_arena.
 * These arenas import memory from the contig_mem_slab_arena one
```

```
 * contiguous chunk at a time.
 *
 * When importing slabs, an attempt is made to allocate a large page
 * to use as backing. As a result of the non-relocatable requirement,
 * slabs are allocated from the kernel cage freelists. If the cage does
 * not contain any free contiguous chunks large enough to satisfy the
 * slab allocation, the slab size will be downsized and the operation
 * retried. Large slab sizes are tried first to minimize cage
 * fragmentation. If the slab allocation is unsuccessful still, the slab
 * is allocated from outside the kernel cage. This is undesirable because,
 * until slabs are freed, it results in non-relocatable chunks scattered
 * throughout physical memory.
 *
 * Allocations from the contig_mem_arena are backed by slabs from the
 * cage. Allocations from the contig_mem_reloc_arena are backed by
 * slabs allocated outside the cage. Slabs are left share locked while
 * in use to prevent non-cage slabs from being relocated.
 *
 * Since there is no guarantee that large pages will be available in
 * the kernel cage, contiguous memory is reserved and added to the
 * contig_mem_arena at boot time, making it available for later
 * contiguous memory allocations. This reserve will be used to satisfy
 * contig_mem allocations first and it is only when the reserve is
 * completely allocated that new slabs will need to be imported.

 * map_addr_proc() is the routine called when the system is to
 * choose an address for the user.  We will pick an address
 * range which is just below the current stack limit.  The
 * algorithm used for cache consistency on machines with virtual
 * address caches is such that offset 0 in the vnode is always
 * on a shm_alignment'ed aligned address.  Unfortunately, this
 * means that vnodes which are demand paged will not be mapped
 * cache consistently with the executable images.  When the
 * cache alignment for a given object is inconsistent, the
 * lower level code must manage the translations so that this
```

```
 * is not seen here (at the cost of efficiency, of course).
 *
 * Every mapping will have a redzone of a single page on either side of
 * the request. This is done to leave one page unmapped between segments.
 * This is not required, but it's useful for the user because if their
 * program strays across a segment boundary, it will catch a fault
 * immediately making debugging a little easier.  Currently the redzone
 * is mandatory.
 *
 * addrp is a value/result parameter.
 *      On input it is a hint from the user to be used in a completely
 *      machine dependent fashion.  For MAP_ALIGN, addrp contains the
 *      minimal alignment, which must be some "power of two" multiple of
 *      pagesize.
 *
 *      On output it is NULL if no address can be found in the current
 *      processes address space or else an address that is currently
 *      not mapped for len bytes with a page of red zone on either side.
 *      If vacalign is true, then the selected address will obey the alignment
 *      constraints of a vac machine based on the given off value.

617  * contig_mem_alloc, contig_mem_alloc_align
618  *
619  * Caution: contig_mem_alloc and contig_mem_alloc_align should be
620  * used only when physically contiguous non-relocatable memory is
621  * required. Furthermore, use of these allocation routines should be
622  * minimized as well as should the allocation size. As described in the
623  * contig_mem_arena comment block above, slab allocations fall back to
624  * being outside of the cage. Therefore, overuse of these allocation
625  * routines can lead to non-relocatable large pages being allocated
626  * outside the cage. Such pages prevent the allocation of a larger page
627  * occupying overlapping pages. This can impact performance for
628  * applications that utilize e.g. 256M large pages.
