  1 # Address Space Layout Randomisation

  3 Briefly, see: ‘psecflags(1)‘, ‘security-flags(5)‘

  5 ## Administration

  7 ASLR is implemented via process security-flags (which we introduce), there are
  8 four sets of flags per-process: The effective, inheritable, upper, and lower
  9 sets (see ‘security-flags(5)‘).  The effective set is immutable, it can only
 10 change when the process calls ‘exec(2)‘, at which point the effective set is
 11 replaced by the inheritable set (with one exception).  Security flags are
 12 inherited upon ‘fork(2)‘ (but the inheritable set is not promoted until
 13 ‘exec(2)‘, as mentioned).  The upper and lower sets bound the permitted values
 14 of the inheritable set.

 16 This is such that a given execution of an executable has a constant set of
 17 security-flags, which simplifies things for everyone.

 19 This unfortunately means that to enable ASLR fully system-wide, requires a
 20 reboot or at least restart of a majority of services.

 22 The system-wide ASLR flag is an SMF property on the new service
 23 ‘svc:/system/process-security‘, which contains ‘default‘, ‘upper‘, and ‘lower‘
 24 property groups, with one boolean property per implemented flag (see, again,
 25 ‘security-flags(5)‘).  These will only affect services (and their children)
 26 started via SMF after the values have been changed.

 28 Per-process setting (and inspecting) of security-flags is done via
 29 ‘psecflags(1)‘.

 31 Per-service setting of security-flags is achievable by the ‘security_flags‘
 32 property on the service ‘method_context‘.  A ‘default‘ pseudo-flag specifies
 33 the flags from ‘svc:/system/process-security‘, and flags can be
 34 added/subtracted from there much the same as with ‘privileges(5)‘.

 36 ## Privilege

 38 A process may change the security-flags of any process to which it could send
 39 a signal with ‘kill(2)‘, as long as the process also has the
 40 ‘PRIV_PROC_SECFLAGS‘ privilege.  This privilege is granted by default, but is
 41 not a ‘basic‘ privilege.  If you have configured custom privileges for certain
 42 users or services, they will not automatically gain the new
 43 ‘PRIV_PROC_SECFLAGS‘ (unfortunately).

 45 ## Executable tagging

 47 There is a somewhat compatible property of dynamic executables, ‘DT_SUNW_ASLR‘
 48 which controls the ASLR behaviour of a given executable.  If this dynamic tag
 49 has a value of 1, ASLR is always enabled for an execution of this process.  If
 50 the tag has a value of 0, ASLR is never enabled for an execution of this
 51 process.  The default is to inherit the ASLR flag as normal.

 53 This allows a process for which ASLR is known to be problematic to explicitly
 54 forbid it, and for processes of special sensitivity to mandate it.

 56 This is controlled via the ‘-z aslr‘ flag to ‘ld(1)‘.

 58
```

```
 59 ## Per-zone configuration

 61 The default security flags for a zone, and the upper and lower limits, may be
 62 specified with the security-flags resource in zonecfg(1M).  These are applied
 63 to every process in NGZs (unlike the GZ, where there are a small number of
 64 processes we must miss)

 67 ## Missing bits/Problems/Worries

 69 ### The stack skewing may skew too much of the stack

 71 At present, we skew the absolute base of the stack, which means the gap
 72 between a user stack frame and the process environment is constant.  I have
 73 this vague memory that that’s sub-par, and that we want to skew the stack
 74 _after_ the environment, etc.  I could be entirely wrong about that though.

 76 ### We skew each mapping separately

 78 Some systems calculate a random skew for the various parts of a process at
 79 execution time, and apply that same skew to each mapping.  That obviously
 80 minimises the performance impact of this significantly for processes that
 81 perform many mappings.

 83 Due to some unfortunate aspects of how we manage the user address space and
 84 mappings, we don’t do that right now.  We calculate a separate random skew for
 85 each mapping we attempt.

 87 ### The way we skew mappings is problematic

 89 The user address space is currently managed somewhat unfortunately (from our
 90 point of view, at least).  When attempting a mapping we first determine the
 91 highest gap into which the requested mapping can fit, and then we place the
 92 mapping at the highest address in that gap.  This is how we manage user
 93 fragmentation.

 95 The current ASLR implementation works in basically the same way.  We still
 96 find the highest gap into which the given mapping may fit, and choose the
 97 highest address at which it may fit.  The only difference is that we then slew
 98 it backward by a random (but co-aligned), amount.

100 This is obviously not as random as it could be, but is the easiest way I’ve
101 found in the current code base for introducing uncertainty while also
102 preserving any attempt at preventing unbounded user fragmentation.

104 It is not impossible to imagine a long-lived process that makes many mappings
105 being in a position where mappings later in its life are 100% predictable
106 given this implementation, however.  In fact, I think it is fairly likely.

108 I think the most at risk would be a process which makes many mappings, and
109 uses ‘dlopen(3c)‘ at unpredictable times (rather than, as is most common, during
110 setup).  Dynamic objects tend to have strict (and high) alignment requirements
111 which in such a process are likely to only be fulfillable at a single location
112 in the address space gap we choose, and thus be entirely predictable.

114 ### Randomisation of executable base addresses requires PIE

116 To randomise the executable base address, we need position independent
117 executables, which appears like it would turn into a whole separate project
118 (though perhaps not too large a project).  That code isn’t here, so the
119 executable base is fixed.

121 This means that rather than return-to-libc one could return-to-executable
122 trivially and successfully, I think.  (That would include using the
123 executable’s PLT to vector yourself to libc.  Should the executable have a PLT
124 entry for something useful to you).
```

```
125 #endif /* ! codereview */
```

# This file provides exceptions to the usual rules applied to ELF objects by
# check_rtime. All strings are Perl regular expressions that are compared to
# file paths. In addition to the standard Perl syntax, there is one extension:
#
#       MACH(dir)
#
# is expanded into a regular expression that matches the given
# directory, or a 64-bit subdirectory of the directory with the
# name of a 64-bit architecture. For example, MACH(lib) will match
# any of the following:
#
#       lib
#       lib/amd64
#       lib/sparcv9

new/usr/src/cmd/sgs/elfdump/common/corenote.c
Code review comments from jeffpc
7029 want per-process exploit mitigation features (secflags)
7030 want basic address space layout randomization (aslr)
7031 noexec_user_stack should be a secflag
7032 want a means to forbid mappings around NULL.

/*
 * Buffer types:
 *
 * Many of the routines in this module require the user to supply a
 * buffer into which the desired strings may be written. These are
 * all arrays of characters, and might be defined as simple arrays
 * of char. The problem with that approach is that when such an array
 * is passed to a function, the C language considers it to have the
 * type (char *), without any regard to its length. Not all of our
 * buffers have the same length, and we want to ensure that the compiler
 * will refuse to compile code that passes the wrong type of buffer to
 * a given routine. The solution is to define the buffers as unions
 * that contain the needed array, and then to pass the given union
 * by address. The compiler will catch attempts to pass the wrong type
 * of pointer, and the size of a structure/union is implicit in its type.
 *
 * A nice side effect of this approach is that we can use a union with
 * multiple buffers to handle the cases where a given routine needs
 * more than one type of buffer. The end result is a single buffer large
 * enough to handle any of the subcases, but no larger.
 */

/*
 * Size of buffer used by conv_invalid_val():
 *
 * Various values that can't be matched to a symbolic definition are converted
 * to a numeric string.
 *
 * The buffer size reflects the maximum number of digits needed to
 * display an integer as text, plus a trailing null, and with room for
 * a leading "0x" if hexidecimal display is selected.
 *
 * The 32-bit version of this requires 12 characters, and the 64-bit version
 * needs 22. By using the larger value for both, we can have a single
 * definition, which is necessary for code that is ELFCLASS independent. A
 * nice side benefit is that it lets us dispense with a large number of 32/64
 * buffer size definitions that build off CONV_INV_BUFSIZE, and the macros
 * that would then be needed.

/*
 * Most conversion routines are able to provide strings in one of
 * several alternative styles. The bottom 8 bits of Conv_fmt_flags_t
 * are used to specify which strings should be used for a given call
 * to a conversion routine:
 *
 *   DEFAULT
 *      The default string style used by a given conversion routine is
 *      an independent choice made by that routine. Different routines
 *      make different choices, based largely on historical usage and
 *      the perceived common case. It may be an alias for one of the
 *      specific styles listed below, or it may be unique.
```

```
 *
 *   DUMP
 *      Style of strings used by dump(1).
 *
 *   FILE
 *      Style of strings used by file(1).
 *
 *   CRLE
 *      Style of strings used by crle(1).
 *
 *   CF
 *      Canonical Form: The string is exactly the same as the name
 *      of the #define macro that defines it in the public header files.
 *      (e.g. STB_LOCAL, not LOCL, LOCAL, LOC, or any other variation).
 *
 *   CFNP
 *      No Prefix Canonical Form: The same strings supplied by CF,
 *      but without their standard prefix. (e.g. LOCAL, instead of STT_LOCAL).
 *
 *   NF
 *      Natural Form: The form of the strings that might typically be entered
 *      via a keyboard by an interactive user. These are usually the strings
 *      from CFNP, converted to lowercase, although in some cases they may
 *      take some other "natural" form. In command completion applications,
 *      lowercase strings appear less formal, and are easier on the eye.
 *
 * Every routine is required to have a default style. The others are optional,
 * and may not be provided if not needed. If a given conversion routine does
 * not support alternative strings for a given CONV_FMT_ALT type, it silently
 * ignores the request and supplies the default set. This means that a utility
 * like dump(1) is free to specify a style like DUMP to every conversion
 * routine. It will receive its special strings if there are any, and
 * the defaults otherwise.
 */

 *
 * Val_desc2 adds v_osabi and v_mach fields to Val_desc, which allows
 * for non-generic mappings that apply only to a specific OSABI/machine.
 * Setting v_osabi to 0 (ELFOSABI_NONE) specifies that any OSABI matches.
 * Similarly, setting v_mach to 0 (EM_MACH) matches any machine. Hence,
 * setting v_osabi and v_mach to 0 in a Val_desc2 results in a generic item,
```

```
 * and is equivalent to simply using a Val_desc.
 *
 * These structs are used in two different contexts:
 *
 * 1)   To expand bit-field data items, using conv_expn_field() to
 *      process a NULL terminated array of Val_desc, or conv_expn_field2()
 *      to process a null terminated array of Val_desc2.
 *
 * 2)   To represent sparse ranges of non-bitfield values, referenced via
 *      conv_ds_vd_t or conv_ds_vd2_t descriptors, as described below.
 */
typedef struct {
        Conv_elfvalue_t v_val;          /* expansion value */
        Msg             v_msg;          /* associated message string code */
} Val_desc;
typedef struct {
        Conv_elfvalue_t v_val;          /* expansion value */

        Half            v_mach;         /* Machine to which entry applies */
        Msg             v_msg;          /* associated message string code */
} Val_desc2;

/*
 * The conv_ds_XXX_t structs are used to pull together the information used
 * to map non-bitfield values to strings. They are a variant family, sharing
 * the same initial fields, with a generic "header" definition that can be
 * used to read those common fields and determine which subcase is being
 * seen. We do this instead of using a single struct containing a type code
 * and a union in order to allow for static compile-time initialization.
 *
 * conv_ds_t is the base type, containing the initial fields common to all
 * the variants. Variables of type conv_ds_t are never instantiated. This
 * type exists only to provide a common pointer type that can reference
 * any of the variants safely. In C++, it would be a virtual base class.
 * The fields common to all the variants are:
 *
 *      ds_type: Identifies the variant
 *      ds_baseval/ds_topval: The lower and upper bound of the range
 *              of values represented by this conv_ds_XXX_t descriptor.
 *
 * There are three different variants:
 *    conv_ds_msg_t (ds_type == CONV_DS_MSGARR)
 *      This structure references an array of message codes corresponding
 *      to consecutive ELF values. The first item in the array is the Msg
 *      code for the value given by ds_baseval. Consecutive strings follow
 *      in consecutive order. The final item corresponds to the value given
 *      by ds_topval. Zero (0) Msg values can be used to represent missing
 *      values. Entries with a 0 are quietly ignored.
 *
 *    conv_ds_vd_t (ds_type == CONV_DS_VD)
 *      This structure employs a NULL terminated array of Val_desc structs.
 *      Each Val_desc supplies a mapping from a value in the range
 *      (ds_baseval <= value <= ds_topval). The values described need not
 *      be consecutive, and can be sparse. ds_baseval does not need to
 *      correspond to the first item, and ds_topval need not correspond to
 *      the final item.
 *
 *    conv_ds_vd2_t (ds_type == CONV_DS_VD2)
 *      This structure employs a NULL terminated array of Val_desc2 structs,
 *      rather than Val_desc, adding the ability to specify OSABI and machine
 *      as part of the value/string mapping. It is otherwise the same thing
 *      as CONV_DS_VD.
 */

/*
 * Relocation (active & output) processing structure - transparent to common
 * code. There can be millions of these structures in a large link, so it
 * is important to keep it small. You should only add new items to Rel_desc
 * if they are critical, apply to most relocations, and cannot be easily
 * computed from the other information.
```

```
626  *
627  * Items that can be derived should be implemented as a function that accepts
628  * a Rel_desc argument, and returns the desired data. ld_reloc_sym_name() is
629  * an example of this.
630  *
631  * Lesser used relocation data is kept in an auxiliary block, Rel_aux,
632  * that is only allocated as necessary. In exchange for adding one pointer
633  * of overhead to Rel_desc (rel_aux), most relocations are reduced in size
634  * by the size of Rel_aux. This strategy relies on the data in Rel_aux
635  * being rarely needed --- otherwise it will backfire badly.
636  *
637  * Note that rel_raddend is primarily only of interest to RELA relocations,
638  * and is set to 0 for REL. However, there is an exception: If FLG_REL_NADDEND
639  * is set, then rel_raddend contains a replacement value for the implicit
640  * addend found in the relocation target.
641  *
642  * Fields should be ordered from largest to smallest, to minimize packing
643  * holes in the struct layout.
644  */

651         Word            rel_flags;      /* misc. flags for relocations */
652         Word            rel_rtype;      /* relocation type */
653 };

655 /*
656  * Data that would be kept in Rel_desc if the size of that structure was
657  * not an issue. This auxiliary block is only allocated as needed,
658  * and must only contain rarely needed items. The goal is for the vast
659  * majority of Rel_desc structs to not have an auxiliary block.
660  *
661  * When a Rel_desc does not have an auxiliary block, a default value
662  * is assumed for each auxiliary item:
663  *
664  * -    ra_osdesc:
665  *      Output section to which relocation applies. The default
666  *      value for this is the output section associated with the
667  *      input section (rel_isdesc->is_osdesc), or NULL if there
668  *      is no associated input section.
669  *
670  * -    ra_usym:
671  *      If the symbol associated with a relocation is part of a weak/strong
672  *      pair, then ra_usym contains the strong symbol and rel_sym the weak.
673  *      Otherwise, the default value is the same value as rel_sym.
674  *
675  * -    ra_move:
676  *      Move table data. The default value is NULL.
677  *
678  * -    ra_typedata:
679  *      ELF_R_TYPE_DATA(info). This value applies only to a small
680  *      subset of 64-bit sparc relocations, and is otherwise 0. The
681  *      default value is 0.
682  *
683  * If any value in Rel_aux is non-default, then an auxiliary block is
684  * necessary, and each field contains its actual value. If all the auxiliary
685  * values are default, no Rel_aux is needed, and the RELAUX_GET_xxx()
686  * macros below are able to supply the proper default.
687  *
688  * To set a Rel_aux value, use the ld_reloc_set_aux_XXX() functions.
689  * These functions are written to avoid unnecessary auxiliary allocations,
690  * and know the rules for each item.
691  */

 916 /*
 917  * Parse the -z assert-deflib option. This option can appear in two different
 918  * forms:
 919  *      -z assert-deflib
 920  *      -z assert-deflib=libfred.so
 921  *
 922  * Either form enables this option, the latter form marks libfred.so as an
 923  * exempt library from the check. It is valid to have multiple invocations of
 924  * the second form. We silently ignore mulitple occurrences of the first form
 925  * and multiple invocations of the first form when the second form also occurs.
 926  *

# Message file for cmd/sgs/libld.

@ MSG_ID_LIBLD

#
# TRANSLATION_NOTE -- Beginning of USAGE message
#       The following messages are the usage messages for the ld command.
#       Tab characters (\t) are used to align the messages.
#
#       Each usage message starts with \t, and if the message has more than one
#               line, the following messages are aligned by 3 tab characters.
#               When you see \n\t\t\t, the first \n is used to change the line,
#               and following 3 tab characters are used to align the line.
#
#       Each usage message option is surrounded by [ and ].  Then the
#       description of the option follows. The descriptions should be aligned,
#       so tab characters are padded as needed after the closing bracket ].
#
#       How to align the messages are up to the translators and the
#       localization engineers.
#
#       In C locale, the first 3 messages would look like the following:
#
#       usage: ld [-6:abc:.....] file(s)
#               [-a]            create an absolute file
#               [-b]            do not do special PIC relocations in a.out
#               [-c file]       record configuration 'file'
```

```

2888          *
2889          *      1) Examine all relocations, insert strings from relocations
2890          *              to the mergeable input sections into the string table.
2891          *      2) Modify the relocation values to be correct for the
2892          *              new merged section.
2893          *      3) Modify the symbols used by the relocations to reference
2894          *              the new section.
2895          *
2896          * These passes cannot be combined:
```

```
2897          *      - The string table code works in two passes, and all
2898          *              strings have to be loaded in pass one before the
2899          *              offset of any strings can be determined.
2900          *      - Multiple relocations reference a single symbol, so the
2901          *              symbol cannot be modified until all relocations are
2902          *              fixed.
2903          *
2904          * The number of relocations related to section merging is usually
2905          * a mere fraction of the overall active and output relocation lists,
2906          * and the number of symbols is usually a fraction of the number
2907          * of related relocations. We therefore build APlists for the
2908          * relocations and symbols in the first pass, and then use those
2909          * lists to accelerate the operation of pass 2 and 3.
2910          *
2911          * Reinitialize the lists to a completely empty state.

3425          * Family member:        .SUNW_cap index         lead symbol index
3426          *
3427          * Dynamic objects:
3428          *                       ELF_C_GROUP             ELF_C_SYM
3429          *
3430          * Family lead:          CAPINFO_SUNW_GLOB       .SUNW_capchain index
3431          * Family lead alias:    CAPINFO_SUNW_GLOB       .SUNW_capchain index
3432          * Family member:        .SUNW_cap index         lead symbol index
3433          *
```

```
3434          * The ELF_C_GROUP field identifies a capabilities symbol.  Lead
3435          * capability symbols, and lead capability aliases are identified by
3436          * a CAPINFO_SUNW_GLOB group identifier.  For family members, the
3437          * ELF_C_GROUP provides an index to the associate capabilities group
3438          * (i.e, an index into the SUNW_cap section that defines a group).
3439          *
3440          * For relocatable objects, the ELF_C_SYM field identifies the lead
3441          * capability symbol.  For the lead symbol itself, the .SUNW_capinfo
3442          * index is the same as the ELF_C_SYM value.  For lead alias symbols,
3443          * the .SUNW_capinfo index differs from the ELF_C_SYM value.  This
3444          * differentiation of CAPINFO_SUNW_GLOB symbols allows ld(1) to
3445          * identify, and propagate lead alias symbols.  For example, the lead
3446          * capability symbol memcpy() would have the ELF_C_SYM for memcpy(),
3447          * and the lead alias _memcpy() would also have the ELF_C_SYM for
3448          * memcpy().
3449          *
3450          * For dynamic objects, both a lead capability symbol, and alias symbol
3451          * would have a ELF_C_SYM value that represents the same capability
3452          * chain index.  The capability chain allows ld.so.1 to traverse a
3453          * family chain for a given lead symbol, and select the most appropriate
3454          * family member.  The .SUNW_capchain array contains a series of symbol
3455          * indexes for each family member:
3456          *
3457          *    chaincap[n]  chaincap[n + 1]  chaincap[n + 2]  chaincap[n + x]
3458          *      foo() ndx    foo%x() ndx        foo%y() ndx     0
3459          *
3460          * For family members, the ELF_C_SYM value associates the capability
3461          * members with their family lead symbol.  This association, although
3462          * unused within a dynamic object, allows ld(1) to identify, and
3463          * propagate family members when processing relocatable objects.

3595     *
3596     *  -   If an interpreter is required always generate a PT_PHDR entry as
3597     *      well.  It is this entry that triggers the kernel into passing the
3598     *      interpreter an aux vector instead of just a file descriptor.
3599     *
3600     *  -   When generating an image that will be interpreted (ie. a dynamic
3601     *      executable, a shared object, or a static executable that has been
3602     *      provided with an interpreter - weird, but possible), make the initial
3603     *      loadable segment include both the ehdr and phdr[].  Both of these
3604     *      tables are used by the interpreter therefore it seems more intuitive
3605     *      to explicitly defined them as part of the mapped image rather than
3606     *      relying on page rounding by the interpreter to allow their access.
3607     *
3608     *  -   When generating a static image that does not require an interpreter
3609     *      have the first loadable segment indicate the address of the first
3610     *      .section as the start address (things like /kernel/unix and ufsboot
3611     *      expect this behavior).

342 <!ATTLIST service_fmri
343         value           CDATA #REQUIRED>

345 <!-- Dependencies -->

347 <!--
348   dependency

350     This element identifies a group of FMRIs upon which the service is
351     in some sense dependent.  Its interpretation is left to the
352     restarter to which a particular service instance is delegated.  It
353     contains a group of service FMRIs, as well as a block of properties.

355     Its attributes are

357         name    The name of this dependency.

359         grouping The relationship between the various FMRIs grouped
360                 here; "require_all" of the FMRIs to be online, "require_any"
361                 of the FMRIs to be online, or "exclude_all" of the FMRIs
362                 from being online or in maintenance for the dependency to
363                 be satisfied.  "optional_all" dependencies are satisfied
364                 when all of the FMRIs are either online or unable to come
365                 online (because they are disabled, misconfigured, or one
366                 of their dependencies is unable to come online).

368         restart_on The type of events from the FMRIs that the service should
369                 be restarted for.  "error" restarts the service if the
370                 dependency is restarted due to hardware fault.  "restart"
371                 restarts the service if the dependency is restarted for
372                 any reason, including hardware fault.  "refresh" restarts
373                 the service if the dependency is refreshed or restarted for
374                 any reason.  "none" will never restart the service due to
375                 dependency state changes.

377         type    The type of dependency: on another service ('service'), on
378                 a filesystem path ('path'), or another dependency type.

380         delete  This dependency should be deleted.

396 <!--
397   dependent

399     This element identifies a service which should depend on this service.  It
400     corresponds to a dependency in the named service.  The grouping and type
401     attributes of that dependency are implied to be "require_all" and
402     "service", respectively.

404     Its attributes are

406         name    The name of the dependency property group to create in the
407                 dependent entity.

409         grouping The grouping relationship of the dependency property
410                 group to create in the dependent entity.  See "grouping"
411                 attribute on the dependency element.

413         restart_on The type of events from this service that the named service
414                 should be restarted for.

416         delete  True if this dependent should be deleted.

418         override Whether to replace an existing dependent of the same name.

545 <!-- Restarter delegation, methods, and monitors -->

547 <!--
548   exec_method

550     This element describes one of the methods used by the designated
551     restarter to act on the service instance.  Its interpretation is
552     left to the restarter to which a particular service instance is
553     delegated.  It contains a set of attributes, an optional method
554     context, and an optional stability element for the optional
555     properties that can be included.

557     Its attributes are

559         type    The type of method, either "method" or "monitor".

561         name    Name of this execution method.  The method names are
562                 usually a defined interface of the restarter to which an
563                 instance of this service is delegated.

565         exec    The string identifying the action to take.  For
566                 svc.startd(1M), this is a string suitable to pass to
567                 exec(2).

569         timeout_seconds [integer] Duration, in seconds, to wait for this
570                 method to complete.  A ’0’ or ’-1’ denotes an infinite
571                 timeout.

573         delete  If in the repository, the property group for this method
574                 should be removed.

                        net_address | net_address_v4 | net_address_v6 | time |
                        astring | ustring | boolean | fmri | uri ) #IMPLIED
        required        ( true | false )       "false" >

<!--
  pg_pattern

    The pg_pattern describes one property group.
    Depending on the element's attributes, these descriptions may apply
    to just the enclosing service/instance, instances of the enclosing
    service, delegates of the service (assuming it is a restarter), or
    all services.

    Its attributes are:

        name    The property group's name.  If not specified, it
                matches all property groups with the specified type.
        type    The property group's type.  If not specified, it
                matches all property groups with the specified name.
        required
                If the property group is required.
        target  The scope of the pattern, which may be all, delegate,
                instance, or this.  'all' is reserved for framework use
                and applies the template to all services on the system.
                'delegate' is reserved for restarters, and means the
                template applies to all services which use the restarter.
                'this' would refer to the defining service or instance.
                'instance' can only be used in a service's template block,
                and means the definition applies to all instances of this
                service.

/*
 * This module contains functions used to bring up and tear down the
 * Virtual Platform: [un]mounting file-systems, [un]plumbing network
 * interfaces, [un]configuring devices, establishing resource controls,
 * and creating/destroying the zone in the kernel.  These actions, on
 * the way up, ready the zone; on the way down, they halt the zone.
 * See the much longer block comment at the beginning of zoneadmd.c
 * for a bigger picture of how the whole program functions.
 *
 * This module also has primary responsibility for the layout of "scratch
 * zones."  These are mounted, but inactive, zones that are used during
 * operating system upgrade and potentially other administrative action.  The
 * scratch zone environment is similar to the miniroot environment.  The zone's
 * actual root is mounted read-write on /a, and the standard paths (/usr,
 * /sbin, /lib) all lead to read-only copies of the running system's binaries.
 * This allows the administrative tools to manipulate the zone using "-R /a"
 * without relying on any binaries in the zone itself.
 *
 * If the scratch zone is on an alternate root (Live Upgrade [LU] boot
 * environment), then we must resolve the lofs mounts used there to uncover
 * writable (unshared) resources.  Shared resources, though, are always
 * read-only.  In addition, if the "same" zone with a different root path is
 * currently running, then "/b" inside the zone points to the running zone's
 * root.  This allows LU to synchronize configuration files during the upgrade
 * process.
 *
 * To construct this environment, this module creates a tmpfs mount on
```

```
 * $ZONEPATH/lu.  Inside this scratch area, the miniroot-like environment as
 * described above is constructed on the fly.  The zone is then created using
 * $ZONEPATH/lu as the root.
 *
 * Note that scratch zones are inactive.  The zone's bits are not running and
 * likely cannot be run correctly until upgrade is done.  Init is not running
 * there, nor is SMF.  Because of this, the "mounted" state of a scratch zone
 * is not a part of the usual halt/ready/boot state machine.

597 /*
598  * The general strategy for unmounting filesystems is as follows:
599  *
600  * - Remote filesystems may be dead, and attempting to contact them as
601  * part of a regular unmount may hang forever; we want to always try to
602  * forcibly unmount such filesystems and only fall back to regular
603  * unmounts if the filesystem doesn't support forced unmounts.
604  *
605  * - We don't want to unnecessarily corrupt metadata on local
606  * filesystems (ie UFS), so we want to start off with graceful unmounts,
607  * and only escalate to doing forced unmounts if we get stuck.
608  *
609  * We start off walking backwards through the mount table.  This doesn't
610  * give us strict ordering but ensures that we try to unmount submounts
611  * first.  We thus limit the number of failed umount2(2) calls.
612  *
613  * The mechanism for determining if we're stuck is to count the number
614  * of failed unmounts each iteration through the mount table.  This
615  * gives us an upper bound on the number of filesystems which remain
616  * mounted (autofs trigger nodes are dealt with separately).  If at the
617  * end of one unmount+autofs_cleanup cycle we still have the same number
618  * of mounts that we started out with, we're stuck and try a forced
619  * unmount.  If that fails (filesystem doesn't support forced unmounts)
620  * then we bail and are unable to teardown the zone.  If it succeeds,
621  * we're no longer stuck so we continue with our policy of trying
622  * graceful mounts first.
623  *
624  * Zone must be down (ie, no processes or threads active).

1763          * get mounted relative to rootpath, which is usually
1764          * <zonepath>/root.  But when mounting a zone for administration
1765          * purposes via the zone "mount" state, build_mounted_pre_var()
1766          * updates rootpath to be <zonepath>/lu/a so we'll mount all
1767          * the zones filesystems there instead.
1768          *
1769          * build_mounted_pre_var() and build_mounted_post_var() will
1770          * also do some extra work to create directories and lofs mount
1771          * a bunch of global zone file system paths into <zonepath>/lu.
1772          *
1773          * This allows us to be able to enter the zone (now rooted at
1774          * <zonepath>/lu) and run the upgrade/patch tools that are in the
```

```
1775          * global zone and have them upgrade the to-be-modified zone's
1776          * files mounted on /a.  (Which mirrors the existing standard
1777          * upgrade environment.)
1778          *
1779          * There is of course one catch.  When doing the upgrade
1780          * we need <zoneroot>/lu/dev to be the /dev filesystem
1781          * for the zone and we don't want to have any /dev filesystem
1782          * mounted at <zoneroot>/lu/a/dev.  Since /dev is specified
1783          * as a normal zone filesystem by default we'll try to mount
1784          * it at <zoneroot>/lu/a/dev, so we have to detect this
1785          * case and instead mount it at <zoneroot>/lu/dev.
1786          *
1787          * All this work is done in three phases:
1788          *   1) Create and populate lu directory (build_mounted_pre_var()).
1789          *   2) Mount the required filesystems as per the zone configuration.
1790          *   3) Set up the rest of the scratch zone environment
1791          *      (build_mounted_post_var()).

/*
 * zonecfg is a lex/yacc based command interpreter used to manage zone
 * configurations.  The lexer (see zonecfg_lex.l) builds up tokens, which
 * the grammar (see zonecfg_grammar.y) builds up into commands, some of
 * which takes resources and/or properties as arguments.  See the block
 * comments near the end of zonecfg_grammar.y for how the data structures
 * which keep track of these resources and properties are built up.
 *
 * The resource/property data structures are inserted into a command
 * structure (see zonecfg.h), which also keeps track of command names,
 * miscellaneous arguments, and function handlers.  The grammar selects
 * the appropriate function handler, each of which takes a pointer to a
 * command structure as its sole argument, and invokes it.  The grammar
 * itself is "entered" (a la the Matrix) by yyparse(), which is called
 * from read_input(), our main driving function.  That in turn is called
 * by one of do_interactive(), cmd_file() or one_command_at_a_time(), each
 * of which is called from main() depending on how the program was invoked.
 *
 * The rest of this module consists of the various function handlers and
 * their helper functions.  Some of these functions, particularly the
 * X_to_str() functions, which maps command, resource and property numbers
 * to strings, are used quite liberally, as doing so results in a better
 * program w/rt I18N, reducing the need for translation notes.
